TUBERCULOUS MENINGITIS IN CHILDREN

A Preliminary Report of Its Treatment With Streptomycin and "Promizole"

EDITH M. LINCOLN, M.D.
THOMAS W. KIRMSE, M.D.
and
ESTELLE DE VITO, M.D.
New York

Sulfones and streptomycin are the first therapeutic agents to provide encouraging results in the management of previously fatal forms of tuberculosis. Since 1944, "promizole" (4,2′-diaminophenyl-5′-thiazolyl sulfone) has been used in the Chest Clinic of the Children's Medical Service, Bellevue Hospital.[1] The use of "promizole' 'in miliary tuberculosis has produced encouraging results. Of 7 patients treated for more than a month, 5 are living and well. Three of these patients have been followed more than three years with no recurrence of the disease and no new manifestations of hematogenous dissemination. However, treatment of tuberculous meningitis with "promizole" alone was unsuccessful. Five successive patients died six to twenty-five days after treatment was begun, and pathologic examination of the brains in 2 cases showed no demonstrable retardation of the disease.

Cooke, Dunphy and Blake [2] were the first to report the use of streptomycin intrathecally in human tuberculous meningitis. The patient, an infant, has survived thirty months since treatment was started but is now mentally retarded and probably deaf. Krafchik's [3] patient, also an infant, relapsed ten months after treatment was instituted. A two month course of streptomycin was repeated, and the patient remained well twenty-one months after the original treatment was started and twelve months after relapse. Mentality and development have been normal. Bornstein [4] treated a 4 year old boy who had miliary tuberculosis. Meningitis developed during convalescence; streptomycin was again administered, but death occurred within a month. Appelbaum's [5] patient was still living and apparently normal fourteen months after streptomycin therapy was started and eight months after therapy was completed. Vignec's [6] patient became deaf while under treatment and died after several months. Craig's [7] patient was treated for five months for miliary tuberculosis but contracted meningitis eighteen days after therapy was completed and died within two weeks. McDermott [8] treated 10 patients with meningitis; 7 died; only 1 is in good clinical remission. Hinshaw and Feldman [9] treated 12 patients who had meningitis; 4 survived; only 1 showed no residual neurologic signs. The Veterans Administration, the Army and the Navy [10] treated 91 patients with meningeal involvement; 33 are living. Only 18 of these are clinically well. In Debré's [11] series of 80 patients, 50 per cent died and not more than 5 per cent of the survivors were in good clinical remission.

M. I. Smith [12] treated infected albino rats with streptomycin and "promin" (sodium p,p-diaminodiphenylsulfone-N,N′-didextrose sulfonate) individually and in combination. He concluded that together these drugs exerted an action greater than might have been anticipated from a simple summation of effects. Cocchi [13] treated 28 patients having meningitis with streptomycin and "promin"; 7 died during treatment.

Because of our encouraging results with "promizole" in miliary tuberculosis, we decided to treat our patients having meningitis with both "promizole" and streptomycin, hoping to utilize the rapid action of streptomycin temporarily and then continue treatment with "promizole," since this sulfone can apparently be given safely and effectively over a period of years.

DOSAGE

"Promizole" was administered orally at six or twelve hour intervals so that the total daily dosage was 0.5 to 1.0 Gm. This daily dose was gradually increased until a blood level of 2 to 3 mg. per hundred cubic centimeters was obtained. As much as 5 Gm. daily has been given. A maintenance dose of 1 Gm. daily may be adequate after the first six months of treatment.

No attempt was made to give streptomycin on a weight basis. The dosage in older or larger children

was quickly increased to 2 Gm. intramuscularly daily in divided doses, usually at six hour intervals, although several patients were treated only twice daily. Infants and small children were given 0.5 to 1 Gm. intramuscularly daily. All patients received 0.1 Gm. of streptomycin intrathecally daily during at least the first week of treatment. We attempted to use streptomycin intrathecally for two months. After one or two weeks technical difficulties in performing daily punctures or toxic manifestations such as increased ataxia, nystagmus or transient strabismus may appear. Streptomycin was then given intrathecally only on alternate days, or the dosage of intrathecal streptomycin was reduced to 0.5 Gm. daily. In most cases, 0.1 Gm. intrathecally on alternate days was well tolerated and only minimal toxic signs occurred. After six weeks, if improvement continued, intrathecal therapy was given only every third or fourth day. In the course of two months from twenty-five to forty intrathecal doses were given, depending on the individual response to therapy. After two months of intrathecal therapy, a weekly, bimonthly or monthly spinal puncture was performed in order to judge the general course of the disease. This is important because of the frequency with which relapses have been reported.

Intramuscular administration of streptomycin was continued for a period of six months. At least 1 of our patients tolerated the initial dose for the entire period without interruption. More often the dosage had to be reduced or discontinued for a few days when severe toxic disturbances occurred. When reinstituted in gradually increasing doses, the maximum dose may be tolerated again without recurrence of the same toxic symptoms.

TOXIC MANIFESTATIONS

The toxic effects of "promizole" have been previously reported.[1] All our patients in this series showed some degree of thyroid enlargement within two to five months. Leukopenia did not occur. No effect on sexual maturation has so far been noted in these patients, nor have there been any other manifestations of "promizole" toxicity.

The most striking toxic effect of streptomycin occurred after intrathecal therapy. One to four hours after streptomycin is given intrathecally, increased ataxia, nystagmus, transient strabismus and vomiting may occur. We have seen it as early as the second day of treatment, but it is more commonly noted after three to four weeks. Some degree of ataxia was apparent in all our patients by the end of three to four weeks. Vomiting was frequent and required discontinuing the drug for several days in 1 of our patients to prevent undue nutritional disturbance. In several others, vomiting occurred daily after one meal, usually breakfast. If the interval between treatment and meals was increased, vomiting was less likely to occur. Three patients had generalized rashes during therapy with streptomycin. One rash was macular, and one erythematous followed by urticaria and associated with eosinophilia; a third child had a transient generalized papular rash during the first month of treatment but eosinophilia was not noted until three months later. These were the only cases in which eosinophilia was observed. One child had transient cylindruria associated with albuminuria during the third and fourth weeks, and the blood nonprotein nitrogen content rose to 53 mg. per hundred cubic centimeters during this period.

Deafness is the most dreaded toxic result of administration of streptomycin. None of our recovered patients are deaf by gross measurement, and this is true of 12 additional children treated with streptomycin for forms of tuberculosis other than meningitis. One patient became blind and deaf during the first month of tuberculous meningitis while being treated. It is impossible to state whether this was due to the disease or to the therapy, but he ultimately recovered from the meningitis with a complete restoration of vision and hearing.

COURSE OF MENINGITIS TREATED WITH STREPTOMYCIN AND "PROMIZOLE"

In preparation for the treatment of tuberculous meningitis by specific agents, a survey of our previous cases was recently undertaken in order to study the natural course of the disease.[14] In order to establish the success of any therapeutic agent, it is important first to be sure of the diagnosis of tuberculous meningitis and exclude the possibility of serous tuberculous meningitis, which has a less serious prognosis. It is also important to make the diagnosis of tuberculous meningitis as early as possible before irreversible neurologic damage has taken place.

Tuberculous meningitis in the first stage is more likely to be diagnosed early when the patient is already under supervision for tuberculosis. Meningitis may be suspected because of vomiting, drowsiness or irritability, but a definite diagnosis can only be made by examination of the spinal fluid. Even when streptomycin has been given early, the child usually passes to the second stage of meningitis and shows some of the neurologic responses associated with tuberculous meningitis, and the course may be similar to that of an untreated patient. The duration of the second stage under treatment may vary from several weeks to several months. The third, or comatose, stage of the disease may develop under treatment and yet be followed by complete recovery. Fever is usually slow to decline but may persist for several months. Loss of weight and weakness usually were pronounced, but the appetite in our cases remained good. On the whole, therapeutic response during the first month of treatment seemed slight. During the second month gain in weight, decline in temperature and an increase in well-being occurred. Toxic manifestations such as ataxia, periodic or severe vomiting, irritability and restlessness may be observed.

In our cases, neurologic signs cleared slowly. Diminished or even absent superficial and deep tendon reflexes may persist throughout the course of treatment and even into the convalescent period. Patient 2 still has a slight internal strabismus seven months after onset of meningitis. Patient 6 shows coarse tremor of both hands four months after diagnosis of meningitis. The sensorium was clouded during the height of the disease in all cases, and 1 patient (patient 5) was blind, deaf and apparently oblivious of his surroundings for over a month. However, none of the patients who recovered from tuberculous meningitis have any signs of mental impairment.

SPINAL FLUID CHANGES IN TREATED PATIENTS

The sugar content of the spinal fluid remained low during the first week or longer, then showed an irregular return to normal in three to twelve weeks. Proteins remained below 250 mg. per hundred cubic centimeters in 5 patients but were very high in 2: 6,200 mg. in patient 1, who died, and 2,100 mg. in patient 6 three weeks after the last intrathecal administration of streptomycin. The protein content of the spinal fluid returned to normal in 5 of our surviving patients within three to five months. Patient 6, five months after onset of meningitis, still has a protein content of over 400 mg. per hundred cubic centimeters. Cell counts were over 1,000 per cubic millimeter at some time in the course of intrathecal therapy in all patients, but had all returned to normal before the end of the fourth month of therapy.

---

REPORTS OF CASES

Case 1.—E. S., a white girl aged 9 months, was admitted Dec. 21, 1946 with a history of fever, poor appetite and vomiting of two weeks' duration. Three days before admission, the child's neck became stiff. A roentgenogram of the chest disclosed right hilar enlargement and infiltration at the base of the right lung. Physical examination revealed a pale, flabby, moderately dehydrated, very unresponsive child. The temperature was 102.6 F. The anterior fontanel was bulging; pupils reacted sluggishly to light. Biot type breathing was present.. There was pronounced nuchal rigidity and the superficial and deep reflexes were hyperactive.

The spinal fluid was clear with 90 cells per cubic millimeter and 76 mg. of protein and 46 mg. of sugar per hundred cubic centimeters. Tubercle bacilli were found on direct examination and culture. In a guinea pig inoculated with spinal fluid extensive tuberculosis developed.

On the second hospital day the child had a generalized convulsion and held the extremities rigidly. Superficial and deep reflexes were absent. Streptomycin and "promizole" were started on December 23 and continued until February 26. Intrathecal streptomycin was continued daily until January 27. Technical difficulties in performing lumbar punctures made it necessary to use the cisternal or ventricular routes thereafter.

For several weeks the child showed increased attentiveness, purposeful motions of the upper extremities and some interest in her surroundings. In early February her general condition became worse. Increased irritability, right internal strabismus and Cheyne-Stokes respiration were present. The temperature rose to 105 F. Death occurred on Feb. 26, 1947. No necropsy was obtained.

The patient received "promizole" orally 1.0 to 1.5 Gm. daily, and streptomycin, 0.6 Gm. intramuscularly daily for sixty-six days and 0.05 to 0.1 Gm. intrathecally for forty days, a total of 42 Gm. of streptomycin (38,000 units per pound [83,700 per kilogram] per diem).

Case 2.—H. R., a Negro boy aged 11 years, was admitted Jan. 28, 1947. For one year he had noticed tenderness over the right forearm and limited motion of the right wrist. At another hospital, the reaction to the Mantoux test was positive to 0.01 mg. of old tuberculin. An abscess at the wrist was aspirated and guinea pigs inoculated with the fluid obtained died of extensive tuberculosis. Draining sinuses developed at the points of aspiration.

On admission to Bellevue Hospital, the patient appeared thin. There was tenderness over the upper dorsal vertebrae and dulness over the right lower part of the chest. Superficial and deep reflexes were active. Roentgenograms disclosed paravertebral infiltration involving the upper thoracic part of the spine, extensive destructive spondylitis involving the fifth, sixth and seventh thoracic vertebrae and a small area of rarefaction in the upper third of the shaft of the right ulna with surrounding osteoid density. The patient was placed on a Bradford frame.

During the first three weeks the temperature varied from 101 to 103 F.; it then declined to around 100 to 101 F. Roentgenograms of the chest taken in March revealed definite miliary infiltration, and "promizole" was started. About one week later the patient complained of headache and occasional vomiting. The temperature, which had been steadily rising for several weeks, reached 105 F. on April 5, and the patient then complained of photophobia, diplopia, increased vomiting and somnolence. Left external strabismus was first noted. The neurologic examination otherwise elicited no abnormality.

In the spinal fluid there were 240 cells per cubic millimeter, predominantly mononuclear, and 100 mg. of protein and 40 mg. of sugar per hundred cubic centimeters. Streptomycin therapy was begun the same day. Signs of meningeal irritation subsided, but an irregular septic type of fever continued until the course of intrathecal streptomycin was completed.

During the acute febrile stage of his illness, the patient lost 11 pounds (5 Kg.), but he has since regained and surpassed his admission weight. The temperature has remained normal the past two months. Serial roentgenograms of the chest showed complete clearance of the miliary tuberculosis two months after antibiotic therapy was started and maximum regression of the paravertebral abscess within three months. The sinus tracts of the right forearm ceased draining after six weeks. The dorsal vertebrae showed no change and the patient was placed in a plaster of paris cast. The thyroid isthmus was palpable, and a mild degree of left external strabismus is still present but does not interfere with vision.

The patient received "promizole" orally, 1 to 5 Gm. daily, and streptomycin, 1.5 Gm. intramuscularly daily, for one hundred and eighty-three days and 0.1 Gm. intrathecally in twenty-four lumbar punctures over a period of fifty-four days, a total of 276.0 Gm. of streptomycin (31,000 units per pound [68,280 per kilogram] per diem).

Case 3.—J. Y. was a white boy aged 4 years. In March 1947 he had a sore throat with headache and a temperature as high as 105 F., which declined to normal in ten days. Two weeks later he had a recurrence of these symptoms, with nose bleeds and pains in the knees; he was admitted to Bellevue Hospital on April 16, 1947 with a diagnosis of rheumatic fever.

Physical examination revealed a well nourished, very pale, mentally alert but acutely ill child. The only abnormalities noted were palpable cervical lymph nodes, slightly injected hypertrophied tonsils and that the liver was palpable 1 cm. below the costal margin. The reaction to the Mantoux test was strongly positive, and a roentgenogram of the chest disclosed miliary tuberculosis. Administration of streptomycin and "promizole" was instituted on April 24. Miliary tubercles were seen in the fundi; tubercle bacilli were found in the blood culture.

After one month the miliary lesions of the lungs appeared definitely decreased in size and number, and two weeks later there was no further roentgen evidence of miliary infiltrations.

By the end of the second month, the temperature had again become elevated. All specific therapy was discontinued for sixteen days, during which time other causes of fever were investigated. The spinal fluid cell count and chemical studies revealed normal values. The temperature remained high and streptomycin was again started. Seven days later the patient complained of headache, photophobia and vomiting. There was pronounced nuchal rigidity associated with a positive Kernig sign, bilateral ankle clonus and absent abdominal reflexes. The spinal fluid was cloudy with 413 cells per cubic millimeter and 124 mg. of protein and 30 mg. of sugar per hundred cubic centimeters. Tubercle bacilli were found by direct examination and on culture of the spinal fluid. "Promizole" and intrathecal streptomycin were instituted.

During the course of combined intramuscular and intrathecal therapy, the acute symptoms subsided rapidly and variable responses were obtained on subsequent neurologic examinations. Occasional vomiting occurred after the course of intrathecal therapy was completed but subsided when the intramuscular dose was reduced. The subsequent course has been afebrile and uneventful. Physical and neurologic examination revealed no abnormality except for a mild ataxia which does not interfere with normal activity and play.

The patient received "promizole" orally, 1 and 1.5 Gm. daily, and streptomycin, 1 to 2 Gm. intramuscularly, for one hundred and seventy-five days; streptomycin, 0.1 Gm., was given intrathecally in thirty-six lumbar punctures during a period of sixty-six days. A total of 229 Gm. of streptomycin was given (55,000 units per pound [121,150 per kilogram] per diem).[15]

Case 4.—L. W., a 3 year old Negro boy, admitted May 3, 1947. A diagnosis of primary tuberculosis was made in January 1947, and under home care the child continued to have fever, easy fatigue, loss of weight and poor appetite. In April he complained of headache and abdominal pain. The symptoms persisted and the patient was hospitalized.

Physical examination revealed a well developed and nourished alert child weighing 32 pounds (13.6 Kg.). The temperature was 103 F., and except for the shotty cervical lymph nodes the general examination revealed no other abnormalities.

On the third hospital day he became irritable and apathetic. The neck was decidedly stiff and bilateral ankle clonus was present. The spinal fluid was cloudy with 188 cells, predominantly lymphocytes, per cubic millimeter and 66 mg. of protein and 23 mg. of sugar per hundred cubic centimeters. A guinea pig inoculated with spinal fluid died of extensive tuberculosis.

Streptomycin and "promizole" were started, and during the next few weeks variable neurologic signs were present. On the twenty-first day of treatment the child had a generalized convulsion. On the twenty-ninth day increased ataxia, nystagmus and facial edema were noted. The liver was palpable 4 cm. below the costal margin. Streptomycin was reduced to 1 Gm. intramuscularly daily.

During the third month excellent clinical improvement was apparent, the neurologic examination was normal, the child gained weight and remained cheerful and playful. The thyroid gland had become definitely palpable. Small doses of desiccated thyroid extract were given, and physical and mental improvement were apparent within a few weeks.

The last three months of treatment were uneventful, and except for a mild degree of ataxia there was no evidence of impairment.

The patient received "promizole," 0.5 to 1 Gm. daily, and streptomycin, 1.5 Gm. intramuscularly daily, which was reduced to 1 Gm. daily during the fifth week. Streptomycin, 0.1 Gm. intrathecally, was given thirty-five times during a period of fifty-six days. A total of 207 Gm. of streptomycin was given in one hundred and ninety days (47,000 units per pound [103.520 per kilogram] per diem).

Case 5.—E. D., a Negro boy aged 2, was admitted May 19, 1947 with a history of fever, swelling of the cervical lymph nodes, cough, nasal discharge and pronounced loss of weight and appetite of three weeks' duration.

Physical examination revealed an emaciated chronically ill child. The temperature was 103.4 F. The reaction to the patch test was positive, and a roentgenogram of the chest disclosed widening of the mediastinum and enlarged left hilar nodes.

On the sixth day, somnolence, nuchal rigidity and hyperactive reflexes were associated with positive Kernig and Brudzinski signs. The spinal fluid was clear with 15 cells per cubic millimeter and 275 mg. of protein and 15 mg. of sugar per hundred cubic centimeters. Acid-fast bacilli were found in the pellicle. Streptomycin and "promizole" were started the same day. The child could be roused to take food and fluids and cried on attempts to move extremities passively. During the third and fourth weeks of his disease, the child became blind and hearing was apparently completely lost. Transient cylindruria and albuminuria appeared and the blood nonprotein nitrogen rose to 53 mg. per hundred cubic centimeters.

During the second month a vegetative, somewhat decerebrate existence continued. The usual course of intrathecal streptomycin was completed. By the fourth month, vision and hearing were restored. The child held his cup and showed evidence of gain in weight and strength. He now stands up in bed, feeds himself, plays with his toys and talks and laughs heartily at games in which the other children engage. Neurologic examination revealed no abnormalities.

The patient received 1 Gm. of streptomycin intramuscularly daily for two weeks, when the dosage was decreased to 0.5 Gm. In one hundred and eighty-five days 101.6 Gm. of streptomycin was given intramuscularly. The drug was given intrathecally thirty-four times in fifty-eight days. Total combined streptomycin was 105 Gm. (25,000 units per pound [55,070 per kilogram] per diem).

Case 6.—S. E., a Negro girl aged 7, was admitted July 7, 1947. For one week she had complained of headache and sleepiness, during which time she became more irritable and feverish and vomited everything that she ate.

Physical examination revealed a lethargic, chronically ill child weighing 31 pounds (14.1 Kg.). There was stiffness of the back and pain on motion of the extremities. Nuchal rigidity was associated with hyperactive reflexes and positive Kernig's and Brudzinski's signs. The reaction to the patch test was positive, and a roentgenogram of the chest disclosed large hilar and mediastinal nodes.

The initial lumbar puncture showed 99 cells, predominantly lymphocytes, per cubic millimeter and 158 mg. of protein and 35 mg. of sugar per hundred cubic centimeters. Streptomycin and "promizole" were started on July 8. Acid-fast bacilli were found in the spinal fluid on the eleventh, twelfth and fourteenth days after therapy was begun. The patient showed slow but steady improvement during the first three weeks, remained conscious at all times and sat up for brief intervals to play with toys.

During the fourth week, increased drowsiness and stiff neck recurred, associated with coarse tremors of the hands. Photophobia, nystagmus and fleeting pathologic reflexes were present from time to time during the next three weeks, suggestive of encephalitis. Cisternal punctures were performed for several days but there was no evidence of block. The patient became disoriented, and streptomycin was discontinued for three days because of severe vomiting.

Streptomycin was reordered with a maximum dose of 1 Gm. intramuscularly daily. This was well tolerated for four weeks with evidence of improvement, when vomiting recurred associated with listlessness and difficulty in speech and swallowing. All treatment was then discontinued. The child at present is weak and still has transient coarse tremor of the upper extremities. Neurologic examination is otherwise negative. She is clear mentally, able to feed herself, draw pictures and play with toys. Although she tires easily, she acts like a child convalescent from a severe illness.

The patient was given "promizole," 1 to 2 Gm. daily, and streptomycin, 1 to 2 Gm. intramuscularly daily. Intrathecal therapy consisted of thirty-seven lumbar and three cisternal punctures over a fifty-eight day period. Total combined streptomycin was 132 Gm. in ninety-six days (58,000 units per pound [127,750 per kilogram] per diem).

Case 7.—O. V., a boy aged 23 months, was referred to the hospital on July 28, 1947 with a diagnosis of primary tuberculosis. Physical examination revealed a healthy well nourished afebrile child weighing 33 pounds (14,969 Gm.). There was dulness in the right side of the chest anteriorly below the fourth rib level. The liver edge and spleen were palpable. A roentgenogram of the chest disclosed widening of the mediastinum to the right and mottling in the lower third of the right lung.

Fever (102 to 103 F.) first appeared during the third week. On the twenty-sixth hospital day, irritability, somnolence, muscle twitching and nuchal rigidity were noted. Hyperactive reflexes and unsustained ankle clonus were present. The spinal fluid was cloudy with 378 cells, predominantly lymphocytes, per cubic millimeter and 124 mg. of protein and 32 mg. of sugar per hundred cubic centimeters. Streptomycin and "promizole" were started on August 22.

Two days later the child was again active and playful and sat up in his crib. Neurologic examinations showed variable responses from day to day. Clinical improvement has been evident throughout most of the course of treatment. The child now weighs 40 pounds (18,144 Gm.), talks clearly, plays vigorously and remains healthy and active. Ataxia is apparent only when blindfolded. Three months of intramuscular administration of streptomycin have been completed (1 Gm. daily); it will be continued for the full six month period. Thirty-seven therapeutic lumbar punctures were performed in fifty-seven days. When treatment is completed, 186 Gm. of streptomycin will have been given by combined therapy (40,000 units per pound [88,110 per kilogram] per diem).

---

[15] On Nov. 19, 1947 routine examination of the spinal fluid of this patient showed a sugar content of 25 mg. per hundred cubic centimeters and a protein content of 52 mg. per hundred cubic centimeters; culture of this fluid was positive for tubercle bacilli. The patient showed no clinical evidence of meningitis. He has been retreated with streptomycin, and subsequent spinal fluid cultures have shown no growth.

COMMENT

Streptomycin has revolutionized our attitude toward tuberculous meningitis. Before this antibiotic was introduced, the outlook was hopeless. This serious prognosis has been modified by the use of streptomycin; some patients have apparently been cured. But it is obvious from the literature that in some cases arrested by streptomycin, relapse and death have occurred; and some patients who survived have extensive residual neurologic damage.

We decided to attempt the treatment of tuberculous meningitis by combining "promizole" and streptomycin in order to avail ourselves of the peculiar advantages each possesses. "Promizole" can be given orally and for a period of years with apparently no serious toxic results. It seems to have an inhibitory action on hematogenous tuberculosis, but clinical evidence of its action is usually delayed until at least six weeks after the drug is first given. Streptomycin acts more quickly but cannot be given orally and is more toxic; there is also evidence that tubercle bacilli may develop resistance to it. Moreover, M. I. Smith has shown in guinea pigs that the use of a sulfone and streptomycin together enhances their action beyond the expected value of either alone.

SUMMARY AND CONCLUSIONS

Seven patients with tuberculous meningitis were treated with streptomycin and "promizole." The first patient died after two months of treatment. Six patients are living three to eight months after treatment was instituted. They are all normal mentally and have no neurologic sequelae except for a mild degree of strabismus in case 2 and transient coarse tremors of the upper extremities in case 6.

Six patients had roentgen evidence of active primary tuberculosis and 2 of these had pulmonary miliary tuberculosis. In 5 patients meningitis developed under observation, in 1 after two months of combined treatment for miliary tuberculosis.

Tubercle bacilli were found in the spinal fluid of 5 patients. In another patient bacilli were obtained by guinea pig inoculation from an accompanying bone lesion but were not demonstrated in the spinal fluid.

No serious toxic effects of "promizole" were noted. All cases showed enlarged thyroid two to five months after treatment was begun. The only constant toxic reaction to streptomycin was ataxia which developed in the third or fourth week after institution of therapy. There is no evidence of auditory impairment in any of our patients.

Our patients have not been under observation long enough to report as cured but we have 6 patients with tuberculous meningitis out of 7 treated patients who have no pronounced neurologic damage and are normal mentally. We are making a preliminary report at this time hoping that other cases will be published in order to increase our knowledge of the treatment of tuberculous meningitis.

INTRATHECAL THERAPY NOT REQUIRED FOR H. INFLUENZAE MENINGITIS

A Report of 28 Cases

ARCHIBALD L. HOYNE, M.D.
and
ROWINE HAYES BROWN, M.D.
Chicago

Since 1939, when Alexander[1] developed specific type B anti-influenzal rabbit serum, interest in influenzal meningitis has been greatly intensified. Many reports of recoveries have been published during the past five years, and much has been written concerning this disease, which was formerly almost universally fatal.[2] Nevertheless, although sulfonamide compounds, specific serum and streptomycin are all valuable therapeutic aids, there is no standard accepted for their application. Those who make use of intrathecal treatment cling tenaciously to the method as an old established custom which cannot be relinquished. However, more than twelve years ago one[3] of us reported on the exclusive use of intravenous therapy for patients with meningitis and demonstrated its advantages, including lowered fatality rates,[4] when large doses of serum were injected and intrathecal therapy was abandoned. Although when first inaugurated this plan applied to meningococcic infections, it was soon found equally effective for all[5] forms of meningitis regardless of the causative organism. But intrathecal treatment has by no means been relegated to the past by most physicians. And many with extensive experience still believe that numerous spinal taps for drainage are necessary in purulent meningitis. Silverthorne and Cameron[6] advised daily lumbar punctures with drainage until at least three successive specimens of spinal fluid are sterile. They referred to meningococcic meningitis. But we are convinced that one[7] spinal tap for diagnosis is sufficient as a rule for any kind of meningitis.

Smith and co-workers[8] reported 28 cases of influenzal meningitis with only 2 deaths, and it is noteworthy that 25 of the 27 patients treated with serum received all or most of it intravenously. Moreover, 1 patient whose spinal fluid cultures remained positive was given serum intrathecally without apparent beneficial effect. These authors expressed the belief that patients with influenzal meningitis should be tapped daily until the spinal fluid cultures have been negative for several days and until the spinal fluid sugar has returned to normal. Such procedures are of scientific interest, as they were during earlier years in the treatment of meningococcic meningitis, but they are not necessary to bring about recovery. Strangely enough,

---

the same authors seemed surprised at the results of their treatment without intrathecal therapy, for they stated, "owing either to chance or to the use of large doses of serum (the patients) seem to recover without intrathecal serum."

Type B anti-influenzal serum has been given intrathecally by many investigators, some of whom reported shock,[9] anaphylactic reactions, hydrocephalus and other complications [10] which were so common during the early days of serum therapy for meningococcic meningitis. In addition, it is sometimes said that even though specific type B anti-influenzal rabbit serum is injected intraspinally [11] every twenty-four hours, or more often, for a period of several days, still positive cultures for Hemophilus influenzae have been obtained from the spinal fluid. Such an occurrence parallels exactly our experience with meningococcic meningitis when intrathecal treatment was routine. Moreover, it seems to us that there is no doubt but that intrathecal treatment prolongs the time required for recovery, and one of us has called attention to that fact.[12]

Edmonds and Neter [11] have expressed the opinion that the matter of intrathecal therapy is still a moot question. Nevertheless, they enumerated many of the ill effects of intrathecal treatment, and most of their recovered patients had serum solely by the intravenous route. They cited 4 cases in which serum was given intraspinally and intracisternally at a time when many micro-organisms were present in the cerebrospinal fluid, a circumstance which these authors intimated was responsible for fatal terminations in all 4 patients. Various difficulties were also encountered with other patients, who received intraspinal therapy. If intrathecal administration of serum is not of value when there are many organisms in the spinal fluid, why then, if given in this manner, should it be beneficial at any stage of the disease? Since 1934 [3b] we have treated without any intrathecal therapy several thousand patients with meningitis of various kinds and the results were remarkably successful. Included among them one [13] of us reported 16 recoveries from influenzal meningitis; of the 16 patients only 3 received intrathecal treatment.

Reporting on the use of specific antiserum intrathecally and intravenously for influenzal meningitis, Blumberg, Tannenbaum and Gleich [14] stated that the mortality rate was reduced only to 72 per cent. In their own series of 11 patients "only 6 died." In two thirds of their fatal cases intrathecal treatment was employed; in more than half of their recoveries it was not.

Although Alexander and co-workers [15] conceded that the time required to sterilize the spinal fluid is quite comparable whether serum is given intravenously exclusively or both intravenously and intraspinally, still they advised intrathecal administration of serum if after a period of several days evidence of satisfactory progress is lacking. Thus they displayed a lack of confidence in exclusive intravenous therapy. But they reported 33 instances in which both routes were followed and the fatality rate was 36.3 per cent, whereas for 17 with intravenous therapy only the fatality was 5.8 per cent.

The National Research Council advised when releasing streptomycin for the treatment of influenzal meningitis that this new antibiotic be injected intrathecally. And Nussbaum, Goodman, Robinson and Ray [16] advocated giving streptomycin intrathecally "in view of the failure of adequate amounts of this new drug to enter the spinal fluid when injected intravenously or intramuscularly."

We believe that intrathecal therapy is totally unnecessary, and it is largely for that reason that we are reporting the 28 cases of influenzal meningitis which are represented in the accompanying table. Our series consists of 16 consecutive cases at Municipal Contagious Disease Hospital and 12 consecutive cases at Cook County Contagious Hospital. One or both of us were in constant attendance on the entire group. There were 2 deaths. The single fatality at Municipal Contagious Disease Hospital occurred in a Negro girl who when admitted with whooping cough was 7 weeks of age. This was an emaciated child who had severe paroxysms of pertussis. After four weeks in the hospital a fever and bulging of the anterior fontanel developed. On that account an intraventricular puncture was made and a milky cerebrospinal fluid was released in which the cell count was 13,000 per cubic millimeter, mostly polymorphonuclear cells. Smear and culture of the spinal fluid revealed type B H. influenzae. After two intraventricular injections of 50,000 micrograms of streptomycin at twenty-four hour intervals, the laboratory reported both smear and culture of the spinal fluid as negative. The total number of intraventricular injections was eight, and intramuscular treatment with streptomycin in doses of 100,000 micrograms every three hours was continued for thirty days. Nevertheless, hydrocephalus developed and the infant died sixty days after the diagnosis of influenzal meningitis was established. The other death occurred at Cook County Contagious Hospital. The patient was a white boy, 12 months old, who entered the hospital with a temperature of 105.2 F. and whose condition was desperate at that time. Examination of the spinal fluid disclosed 1,770 cells per cubic millimeter, nearly all polymorphonuclear; both smear and culture of the spinal fluid were positive for H. influenzae. He received 50,000 micrograms of streptomycin intrathecally and 600,000 micrograms intramuscularly, but death ensued within thirteen hours of admission to the hospital.

All our patients in Municipal Contagious Disease Hospital were treated during the period from June 1946 to January 1947, inclusive; the Cook County Contagious Hospital group constituted all the patients with influenzal meningitis who were admitted during 1946. As may be seen in the table, 5 patients were less than 1 year of age. Twenty were boys and 8 girls.

There were 4 Negroes. Only 3[17] of the recovered patients at Municipal Contagious Disease Hospital received streptomycin intrathecally. This route was adopted on the recommendation of the National Research Council, which provided the remedy for these particular patients. In the County Hospital group 3 patients also received streptomycin intraspinally, and this number included the single fatality. Of the entire 28 patients, 18 were treated with streptomycin. Among these 18 there were 7 who received the antibiotic intraspinally; the remaining 11 were treated entirely by the intramuscular route. Only one relapse was encountered, and this occurred in the County Hospital group; the patient received type B anti-influenzal serum but no streptomycin. Every patient was given a sulfonamide drug irrespective of any other treatment.

Among the complications observed was hydrocephalus in the infant with whooping cough who died. Another patient had a left hemiplegia. He was seen several months after his release from the hospital and the condition seemed to be undergoing progressive improvement. An infant had paralysis of the left side of the face which cleared up. In addition 2 patients each had weakness of the left arm. It is interesting to note that in all 4 cases the paresis or paralysis occurred on the left side of the body. There was a single example of deafness which seemed to be complete. The child concerned, 2½ years of age, was treated with streptomycin for nine days, and whether the drug played any part in this complication is extremely doubtful.

Several of the patients were of special interest. The 7 week old baby (case 1) with whooping cough has been referred to. Another Negro infant, 7 months old (case 2) and also convalescing from whooping cough for which we had treated her, returned to the hospital forty-two days after release. Examination revealed the presence of fever and a tense fontanel. A lumbar puncture was made and a cell count of the spinal fluid found to be 11,000 per cubic millimeter; smear and culture revealed type B H. influenzae. This child was treated with streptomycin intramuscularly and recovered.

Patient 13 was admitted with influenzal meningitis approximately two months after his brother had been released from Munipical Contagious Disease Hospital after treatment for laryngotracheobronchitis which had required a tracheotomy. It was not determined whether there was any relationship between the infections in these siblings.

Patient 14 was sent to Municipal Contagious Disease Hospital for intubation because laryngeal diphtheria was suspected. The boy's temperature was 106 F., he was pale, lips cyanotic, and there were decided

[17] Hoyne, A. L.; Brown, R. H., and Drucker, A. P.: Influenzal Meningitis Treated with Streptomycin: Report of Three Cases with Recovery, Arch. Pediat. 63: 559 (Nov.) 1946.

retractions of abdominal, intercostal and supraclavicular areas with each inspiratory effort. On palpation he was found to have pronounced edema about the glottis, and it was apparent that an intubation would not suffice. There was not sufficient time for laryngoscopic inspection. His condition was critical, and we performed a tracheotomy at once, which afforded immediate relief. Blood was obtained for culture, for, on the basis of past experience we surmised that he might be suffering from H. influenzae bacteremia. There was no stiffness of the neck, nor were there any neurologic signs to suggest the possibility of meningitis. Nevertheless, on the following day, although his temperature had fallen to 101 F. and his general condition appeared excellent, he was placed on streptomycin therapy before the report of the blood culture had been received. Twenty-four hours later there was a sharp rise in temperature, nuchal rigidity was present, and a lumbar puncture was made. The cell count of the spinal fluid was 5,760 polymorphonuclear cells per cubic millimeter. In the meantime the blood culture was reported positive for H. influenzae, and the smear and culture of the spinal fluid also proved to be positive. He made an excellent recovery.

Another interesting case was case 19. This patient was a girl aged 18 months who was sent to the County Contagious Hospital as probably having poliomyelitis. She had a temperature of 103.6 F. on admission, with a history of nine days of illness. There was no paralysis and scarcely more than a suspicion of nuchal rigidity. A lumbar puncture revealed 662 cells, nearly all lymphocytes, in the spinal fluid. The Pandy test was positive, and smear and culture of the spinal fluid were reported negative, as was also a blood culture. She continued to have pyrexia and became more and more irritable. Three days after admission a second spinal tap was made and the cell count was 666, and still mostly lymphocytes. At this time the spinal fluid sugar was 24 mg. per hundred cubic centimeters, in contrast to the original report of 18 mg. She had been receiving sulfadiazine because of possible pneumonia. Again smear and culture of the spinal fluid were reported negative. The child was not making good progress and fever continued, as well as an increasing degree of irritability. Therefore a third lumbar puncture was made; this was October 8, six days after her admission. On this third occasion there were many polymorphonuclear cells, but although no organisms were found on smear the spinal fluid culture was positive for H. influenzae. The child was treated with streptomycin on five occasions intrathecally in addition to intramuscular injections. The streptomycin given intrathecally was in four doses of 50,000 micrograms and one dose of 100,000 micrograms. The intramuscular injections consisted of 150,000 micrograms every three hours for twenty-seven days. The total period of hospitalization was forty-five days, and at the end of that time her recovery appeared to be complete without any complications. We believe that her progress would have been more rapid without intrathecal treatment.

In nearly all our cases the dosage of streptomycin intramuscularly consisted of 100,000 micrograms every three hours. The average number of days of streptomycin treatment was 5.9 at Municipal Contagious Disease Hospital, and at County Contagious Hospital 17.2. The latter figure, however, is misleading because 1 patient (no. 19) in whom a late diagnosis was made was treated for twenty-seven days before recovery. The average total dose for recovered patients at Municipal Hospital was 4.6 Gm., whereas the average at the County Hospital was 20.9 Gm. The latter figure is undoubtedly excessive. All but 2 of the patients received sulfadiazine; 1 had sulfapyridine, and 1 sulfathiazole. In nearly every case the initial dose of the sulfonamide compound was given intravenously. For the purpose of forestalling the possibility of a relapse the sulfonamide compound was not discontinued as a rule in less than three weeks from the beginning of treatment.

Although specific type anti-influenzal serum was given to 11 patients it is our opinion that this form of therapy is not necessary when the dosage of streptomycin and the sulfonamide drug is adequate. In fact, it seems probable that satisfactory recoveries may often be brought about by the intramuscular injection of streptomycin alone, just as may occur when patients are treated exclusively with sulfonamide drugs (cases 10, 15, 17, 20 and 22). Alexander, Leidy, Rake and Donovick[18] have reported 12 recoveries in which treatment was exclusively with streptomycin. However, in every one of these instances they gave streptomycin intrathecally as well as intramuscularly. We placed a high value on Alexander's serum prior to the availability of streptomycin, but always gave it intravenously and never injected anti-influenzal serum intrathecally. Alexander and co-workers,[15] in discussing the use of specific type anti-influenzal serum, commented on the fact that although the specific serum was injected intrathecally for several days positive cultures for the infecting organisms were still secured from the spinal fluid. Their statement is reminiscent of the days of intrathecal therapy for meningococcic meningitis. Considering the many disadvantages of serum therapy, not forgetting cost as well as the possibility of serum reactions, we believe that finally serum for influenzal meningitis will seldom be used when streptomycin is available.

SUMMARY

Twenty-eight consecutive cases of influenzal meningitis with 2 deaths, or a fatality of 7 per cent, are reported. The patient who died soon after hospitalization being excluded, the corrected fatality rate is 3.7 per cent for 27 patients.

Sixteen of the patients were at Municipal Contagious Disease Hospital and 12 at Cook County Contagious Disease Hospital. There was a single fatality in each group. One death occurred in a 7 week old infant who was also suffering from whooping cough and developed hydrocephalus. The other was a year old infant admitted to County Hospital in a moribund condition, who died within thirteen hours.

Eighteen of the 28 patients were treated with streptomycin. Twelve patients received streptomycin but no serum. Eleven patients were given streptomycin intramuscularly but had no intrathecal treatment; 10 of these had no serum therapy. Seven were given streptomycin intrathecally as well as intramuscularly, and among these occurred the two deaths. Five patients received serum but no streptomycin.

---

[18] Alexander, H. E.; Leidy, G.; Rake, G., and Donovick, R.: Meningitis Due to Hemophilus Influenzae, J. A. M. A. **132**: 434 (Oct. 26) 1946.

Six patients were treated with serum, streptomycin and a sulfonamide compound. Five patients were treated with a sulfonamide compound exclusively; the drug for all 5 of these was sulfadiazine, although in 2 instances the initial dose was sulfathiazole.

Fifteen of the patients each had only one lumbar puncture. One patient had no spinal tap. The average number of lumbar punctures for the recovered patients was 2.0.

Seventeen (85 per cent) of 20 patients had positive blood cultures. All patients with the exception of the one who had no spinal puncture had positive smears or cultures from the spinal fluid. In all 28 patients the organism was shown to be type B Hemophilus *influenzae*.

Every patient was given a sulfonamide compound. Sulfadiazine was used in 21 instances; sulfadiazine and sulfathiazole in 5, and in the 2 other cases sulfathiazole and sulfapyridine were used singly. None of the patients had any petechiae. There was only one relapse, which occurred in a serum-treated patient. The complications included deafness in 1 patient, hydrocephalus in 1, left hemiplegia in 1, left facial paralysis in 1, paresis of the left arm in 2 and serum sickness in 4.

CONCLUSION

In our series of 28 patients, 21 of the 26 who recovered received no intrathecal therapy. These results should be regarded as additional evidence that intraspinal treatment is not a necessity for the successful management of influenzal meningitis.

On the basis of a dozen years of experience in the treatment of meningitis without intrathecal therapy, it seems certain that recovery is more prompt and complications are fewer when intrathecal treatment is omitted. It may be repeated that the primary purpose for a lumbar puncture should be to establish a diagnosis. Frequent intrathecal taps are of no benefit to the patient. We believe that intrathecal therapy is contraindicated for Type B H. influenzae meningitis.

NOTE: Since completion of this paper 2 additional patients were admitted to Cook County Contagious Hospital in 1947, and both recovered. This makes 14 consecutive patients with influenzal meningitis at County hospital and 16 at Municipal hospital with 1 death in each group, or a fatality rate of 6.6 per cent for 30 patients.

3026 South California Avenue.

Nothing More Dramatic in Medicine.—Liver and liver extracts affect the stroma of erythrocytes only. This verified Whipple's idea expressed in 1922 that there is a scarcity of stroma-building material in pernicious anemia. With adequate liver therapy the blood of a patient about to die rapidly responds and returns completely to normal. The glossitis and other gastrointestinal symptoms disappear entirely. The neurologic symptoms become improved or do not progress; at times they disappear entirely. There is nothing more dramatic in medicine than the effect of liver therapy on a patient with pernicious anemia. Only the use of sulfa drugs and other antibiotics such as penicillin afford such brilliant results. It was found that a liver extract acted just as well as whole liver. Extracts have been improved until now these are almost perfect in their action. A monthly injection of a potent extract will keep the blood normal and prevent the development of a neurologic lesion. An extract of normal gastric mucosa has a similar action, as one would expect from Castle's discovery.—Haden, Russell L., M.D., Pernicious Anemia from Addison to Folic Acid, *Blood, The Journal of Hematology*, page 22, Jan[illegible]

PRACTICAL ASPECTS OF ALLERGIC RHINITIS

LEO H. CRIEP, M.D.
Pittsburgh

Every physician is familiar with the plight of the patient who seeks help because of recurring perennial nasal obstruction, accompanied with profuse thin watery nasal secretion, postnasal discharge, sneezing and loss of sense of taste and smell. Patients may be young or old. Children so afflicted are prone to experience itchiness of the nose and develop mannerisms such as sniffling, nose wrinkling and nose rubbing (fig. 1). The condition is frequently associated with bronchial asthma. One practitioner after another is consulted and then, often, a rhinologist, allergist or even a psychiatrist. The diagnosis may be hyperesthetic or vasomotor rhinitis. However, if certain criteria for allergic diagnosis are present, then the condition is referred to as allergic rhinitis. These criteria include the presence of a family history of allergy, a personal history of other allergic manifestations (asthma, hay fever, eczema), blood and nasal eosinophilia, a history of clinical sensitivity and response to the administration of antihistaminic drugs and epinephrine. Inspection of the nose reveals a characteristic bluish gray appearance and reversible bogginess and edema. The turbinates are swollen. The nasal cavities are reduced in size and are frequently obstructed by mucous polypi. Unfortunately, the diagnosis is not always made early. The patient himself may think that he is subject to

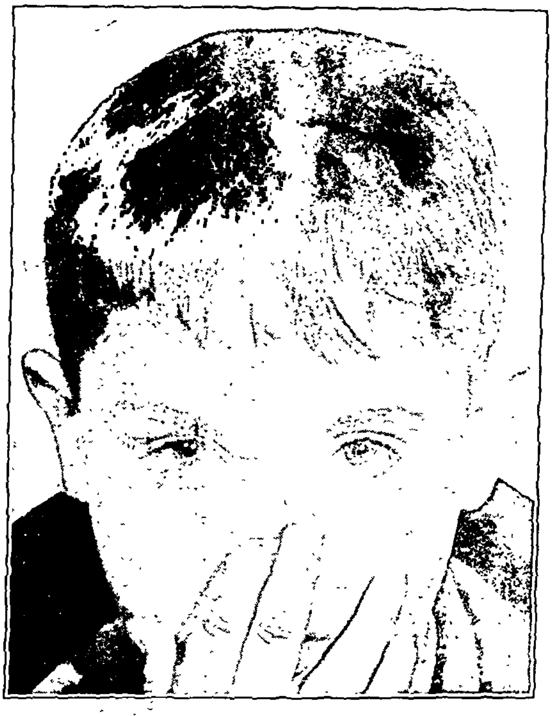

Fig. 1.—Nose rubbing as a mannerism in a child with allergic rhinitis. (From Criep, L. H.: Essentials of Allergy, Philadelphia, J. B. Lippincott Company, 1945.)

From the Division of Allergy, Department of Medicine, School of Medicine, University of Pittsburgh and the Montefiore Hospital, Pittsburgh.

Read before the Section on Miscellaneous Topics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June [illegible] "recurrent colds" or chronic sinusitis. This latter diagnosis is often suggested because localized edema of the mucous membranes produces on transillumination and in roentgenograms of the sinuses transient shadows which are indistinguishable from those of hypertrophic and suppurative sinusitis.

DIFFERENTIAL DIAGNOSIS

Allergic rhinitis is easily differentiated from a common cold by the presence of the aforementioned criteria, by the absence of contagiousness and by its chronicity.

Chronic nasal and sinusal infection present none of the local characteristics of allergic involvement. The nasal mucous membrane in these instances is inflamed and red. Pus may be observed in the nasal cavity. The nasal smear contains a preponderance of polymorphonuclear leukocytes rather than eosinophils. Transillumination and roentgenograms show persistent opacities.

NORMAL FUNCTIONING

The nose is a functioning organ and not merely a passageway to convey air to the lungs. The inspired air must be cleaned, warmed and moistened properly before it is introduced into the delicate pulmonary alveoli. These functions are accomplished by the vibrissae of the nasal vestibule, by the nasal cilia, which constantly sweep toward the pharynx the blanket of mucus secreted by the mucosal glands, and, finally, by the vascular turbinates (fig. 2 and 3).

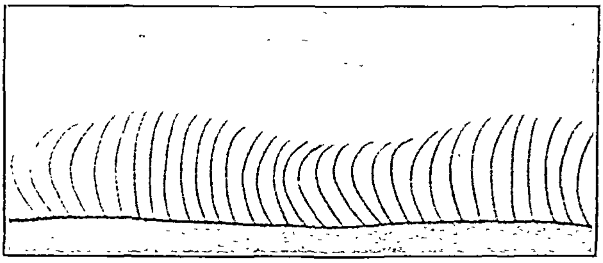

Fig. 2.—Ciliary beat. (Provided by Ciba Pharmaceutical Products, Inc.)

PATHOLOGIC FUNCTIONING

This normal functioning is altered as a result of allergic involvement. Local edema, hypertrophy and hyperplasia of the turbinates interfere with nasal drainage and ventilation (fig. 4 and 5). Normal nasal function is further affected if the cilia are injured by drugs, by chilling and by improperly humidified inspired air. Such damage renders the tissues more susceptible to infection. In young children the bony structure of the hard palate is also affected, producing the high arched palate, "Gothic arch," and dental deformities (fig. 6).

Under normal conditions the mucus secreted by the glands of the sinusal membrane is emptied through the ostiums into the nose. With the advent of allergic edema and increased activity of the mucous glands, this secretion becomes more gelatinous, and when expelled it falls in globular form into the nasopharynx, giving the patient the disagreeable sensation of postnasal "drip." Since the reaction is reversible, changes occur in the character and amount of mucus in the sinuses; the swollen and occluded ostiums do not function normally, and the air within the sinuses may become compressed or rarified. As a result of such fluctuations in air pressure, the patient may experience typical paroxysmal headache.

A discussion of the altered functioning responsible for nasal allergy would be incomplete without mention of the role played by the parasympathetic nervous system. This action, in all likelihood, is linked to the cholinergic effect of histamine or histamine-like substances, presumably released in persons with allergic disease by exposure to specific allergens. This release produces increased capillary dilatation and permeability, with resulting extravasation of fluid and edema of the mucous

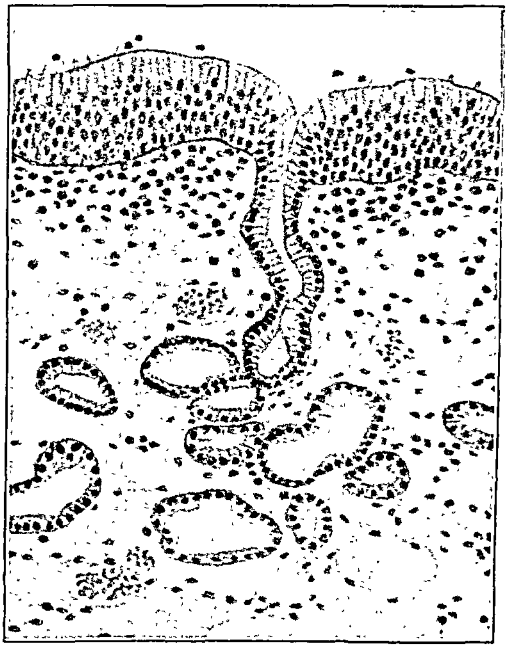

Fig. 3.—Normal nasal mucous membrane. (Provided by Ciba Pharmaceutical Products, Inc.)

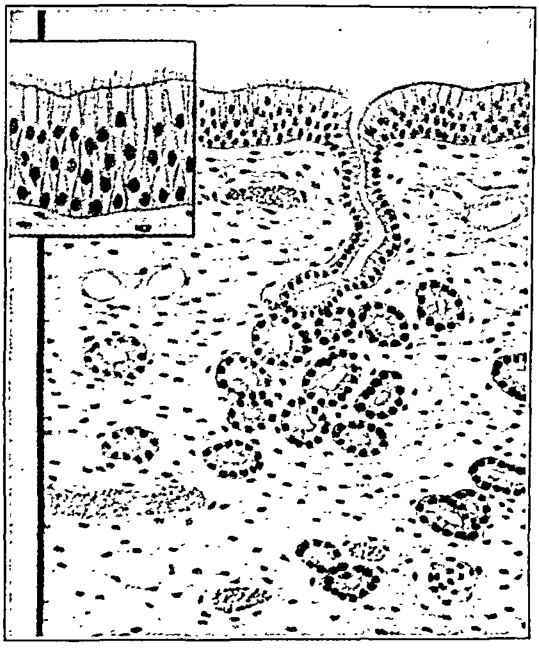

Fig. 4.—Allergic reaction in nasal mucous membrane. (Provided by Ciba Pharmaceutical Products, Inc.)

membranes. Since the central nervous system has a decided influence on the parasympathetic nervous system, it is obvious that emotional upsets wil profoundly affect the symptoms of allergic rhinitis.

PATHOLOGIC CHANGES

Certain pathologic changes occur as a result of altered nasal functioning. These include hypertrophy and hyperplasia of the connective tissue and epithelial cells, which assume the appearance of goblet cells. Pedunculation of the lining membrane produces polypoid degeneration. The polypi are of the mucous variety. The basement membrane is thickened. The cilia are destroyed. There occurs infiltration with lymphocytes, eosinophils and fibroblasts. Infection often supervenes.

CAUSATIVE FACTORS

Allergic rhinorrhea is affected by such endocrine factors as pregnancy and menstruation, by climatic conditions, by irritating fumes and chemicals, by emotional factors and by nasal obstruction and infection.

But the underlying causative factor in all these instances is exposure to a substance to which the patient is sensitive. This may be an inhalant, a food, drug, physical agent or bacterium. If the inhalant is a pollen, then the symptoms are seasonal and the conditicn is referred to as pollen allergy or hay fever. However, seasonal allergic rhinitis may also be produced by the spores of certain molds, particularly stem rust and Alternaria and Hormodendrum organisms. These spores prevail throughout the country, but more so in the central states; they are seen particularly in the spring, summer and early fall. Other frequent inhalant allergens are animal danders (horse dander, feathers, rabbit hair, cat hair, dog hair), orris root, wool, insecticide, cotton linters and house dust. Milk, eggs and wheat are important food allergens. Next in order are fish, nuts and some vegetables and fruits. There are many reports of nasal allergy due to the ingestion, injection or local nasal application of drugs. Among these must be mentioned coal tar and benzol derivatives (acetylsalicylic acid and phenyl salicylate), the halogens (iodides and bromides) and various other drugs. Topical agents of special interest are the sulfonamide drugs, penicillin and "argyrol" (a silver vitellin preparation). I have seen several patients with allergic disease who experience intense and prolonged nasal reactions from the local instillation of these drugs. "Argyrol," which is used so much by rhinologists, is not an infrequent offender. Patients receiving "argyrol" tampons often protest about the discomfort its application causes them; in many instances this discomfort is not recognized as a manifestation of an allergic state. Heat, sunlight and cold are physical agents to which some patients react with allergic nasal manifestations. Cold is of particular importance as a causative agent. Symptoms are commonly present in the morning as the patient steps out of bed. The sudden transition from the warm bed to the chilled air of the room produces nasal edema. This may be due either to allergy to cold or to reflex congestion of the nasal mucous membrane brought about because cooled air passing through the nasal chambers needs to be warmed. There are some who state the belief that nasal allergy may also result from sensitivity to the proteins of bacteria present in nasal infection.

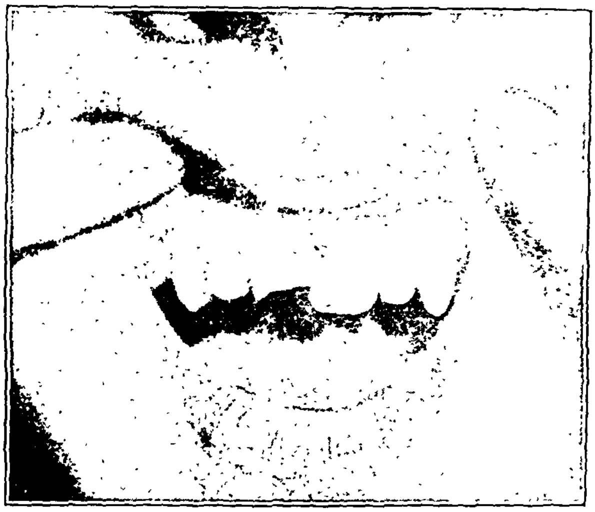

Fig. 6.—Dental deformities in allergic rhinitis.

ETIOLOGIC DIAGNOSES

The etiologic diagnosis establishes which of the aforementioned agents produce the patient's symptoms. It is made on the basis of a carefully taken history and special sensitization tests. The former often gives important diagnostic clues. The sensitization tests include cutaneous tests, ophthalmic tests and nasal or sniff tests. The uses and limitations of cutaneous tests (scratch and intradermal) cannot be discussed in this paper, except to mention that, if properly performed,

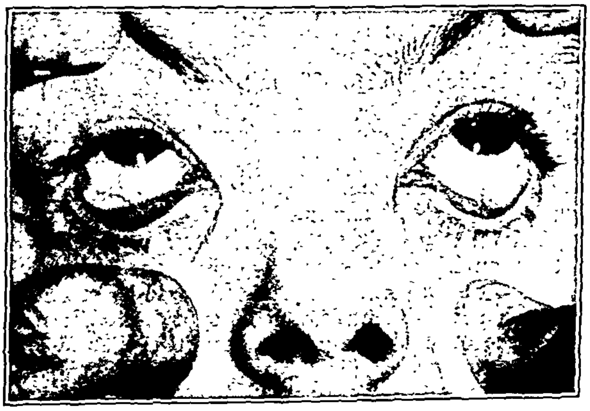

Fig. 7.—Positive reaction to an ophthalmic test in a patient with allergic rhinitis and conjunctivitis. (From Criep, L. H.: Essentials of Allergy, Philadelphia, J. B. Lippincott Company, 1945.)

with allergens which are biologically potent, and if critically interpreted, these tests form an important link in the chain of evidence which may unearth the cause of the allergy. The ophthalmic test (fig. 7) consists in the instillation of a drop of the suspected material in the conjunctival sac. A positive reaction is manifested by local itching, congestion and lacrimation. One may reproduce the clinical manifestations by having the patient sniff a few grains of the suspected substance. If foods are suspected of playing a causative role, the patient is given trial or elimination diets, diets which include only four or five foods. The effect on the patient's clinical condition of enlarging the diet by supplying additional foods is noted.

TREATMENT

Treatment is divided into specific allergic therapy (avoidance and hyposensitization), medicinal measures, attention to nasal infection (topical and surgical) and psychotherapy.

The patient is instructed to avoid allergic factors, to prepare and maintain dust-free rooms and to use allergen-proof pillow slips. A diet is given from which are eliminated the foods to which the patient is sensitive. Hyposensitization with increasing doses of autogenous extract of house dust or with extracts of fungi is undertaken. Irritating fumes (gasoline, paint) and noxious occupational factors are also avoided.

Medicinal treatment is intended to produce palliative relief. This includes the oral administration of 0.375 grain (24.4 mg.) of ephedrine and 0.167 grain (10.8 mg.) of phenobarbital every four hours when necessary. Antihistaminic drugs may be helpful. These include several preparations which vary in effectiveness as well as frequency of undesirable side effects with different patients. The following agents may bring symptomatic relief: "neoantergan," 50 mg. every four hours, and "thephorin" (2-methyl-9-phenyl-1, 3, 4, 9 tetrahydroindeno [2.1-c] pyridine), 50 mg. every four hours. Some patients experience sleeplessness from its administration. "Thenylene" (N,N′-dimethyl-N′-[alpha pyridyl]-N′-[alpha thenyl] ethylenediamine), 50 to 100 mg. every four hours, is an effective histamine antagonist, producing occasional drowsiness. "Benadryl hydrochloride" (beta-dimethylamino-ethyl benzohydryl ether hydrochloride), 25 to 50 mg. and "pyribenzamine hydrochloride" (pyridyl N′-benzyl N-dimethyl ethylenediamine), 25 to 50 mg. every four hours, may also be prescribed. If side effects, such as drowsiness, palpitation, nausea and vomiting, occur, treatment with these drugs should be discontinued. Local vasoconstrictors, most of which contain ephedrine or epinephrine derivatives, should be used sparingly, for it has been established that their continued use is followed by secondary congestion and intensification of symptoms. If nasal drops are ordered, the patient should be instructed in their proper use, employing the Proetz position.

Local nasal pathologic changes and mechanical obstructions, such as deflected septums, polypi and hyperplastic tissue, must be removed in order to restore nasal function, for this not only affords symptomatic relief but helps prevent nasal and sinusal infection, a frequent complication of untreated and unrecognized nasal allergy. Rhinologic treatment should always be conservative at first, especially if there is a decided allergic factor.

Cauterization with trichloracetic acid and electrocoagulation are procedures which have afforded temporary relief at times. Ionization of the nasal membrane is not only not beneficial but harmful. Roentgen ray therapy to the nose is of doubtful value. Radon or radium therapy or roentgen therapy to the nasopharynx is helpful in the presence of associated lymphoid hyperplasia and infection in that region. Tonsillectomy is not specifically indicated.

It is obvious, therefore, that good therapeutic results are predicated on the closest possible cooperation between allergists and rhinologists, with the realization that a considerable percentage of patients suffering with nasal symptoms are allergic and that failure to recognize early and treat properly the allergic state in these patients accounts for many therapeutic failures. On the other hand, many patients suffering with allergic rhinitis will fare better if given the benefit of rhinologic attention.

Allergic rhinitis of long standing produces profound emotional changes: Appetite is impaired; losses in weight occur; sleep is disturbed; work and efficiency are interfered with, and the patient is not well. It is equally true that emotional upheavals frequently increase the severity of the nasal symptoms. Hence, there is necessity for proper evaluation and understanding of allergic patients as human beings.

Allergic and rhinologic attention, coupled with psychotherapeutic measures, will therefore increase the number of satisfactory therapeutic results obtained in patients with allergic rhinitis.

1004 May Building.

ABSTRACT OF DISCUSSION

Dr. Theodore L. Squier, Milwaukee: Allergic rhinitis frequently is the precursor of asthma, as stated by Dr. Criep. Early differentiation of atopic from infectious rhinitis, followed by suitable treatment, can prevent the development of this incapacitating complication in a large number of patients. Accurate diagnosis, therefore, is essential. The value of a carefully taken history cannot be overstressed. Although the limitations of cutaneous testing were not especially emphasized, the need for confirmatory evidence by clinical trial or observed reaction was suggested. Cutaneous tests, subject at best to many inadequacies and technical errors, must always be correlated with the history. Only then can this valuable diagnostic procedure give reliable information. When the nostrils of patients with allergic rhinitis are tightly occluded, as if with a clothespin, emotional upsets are understandable. Violent snorting and blowing is frequent, although patients recognize that the resultant mechanical irritation serves only to increase the discomfort. In such circumstances physicians are tempted to overemphasize psychic factors and overlook the underlying somatic reactions actually responsible for symptoms. Nose drops of various kinds, prescribed for temporary relief, are used with increasing frequency because of the momentary relief afforded. Dr. Criep spoke of the prolonged nasal reactions from local medication which are sometimes observed. Repeatedly, I have seen patients in whom mild seasonal allergic rhinitis persisted long after contact with the specific causative agent had ceased, because of the continued use of nose drops. Occasionally hypersensitivity to one of the chemical constituents of the nose drops is responsible. More often there is only mechanical irritation, with consequent damage to the nasal mucosa, which then appears pale and waterlogged. The appearance of the overmedicated nose is indistinguishable from that during acute allergic episodes. Such patients will not obtain symptomatic relief until nose drops are discarded and local irritation is ended.

FUNDAMENTALS OF PHYSICAL MEDICINE OF INTEREST TO GENERAL PRACTITIONERS

STEVEN M. HORVATH, M.S., Ph.D.
Philadelphia

Adequate and successful use of physical agents can be expected only if there is understanding of the basic physiologic concepts underlying their use and application. It would be impossible to discuss here the basis for all of the modes of treatment employed in physical medicine. Therefore, this paper is being limited and is designed primarily to present some of the information that has been and is being accumulated in experimental work.

The agent most commonly employed in physical medicine is heat. Despite wide application of heat in the treatment of many conditions, its physiologic effects are poorly understood. Two factors must always be considered in heat therapy: (*a*) the amount of heat successfully applied to the tissues, i. e., the resultant of heat input and heat loss, and (*b*) the extra amount of heat produced in the tissues as a consequence of oxidative processes which have been accelerated by the applied heat. Too often these complementary phenomena have been neglected in the analysis of heat therapy.

Heating by conduction is the commonest method. There is an exchange of molecular energy from the warmer object to the cooler, which is achieved only by contact. Since conductive heating is frequently employed in home treatments, the superiority of paraffin in producing prolonged hyperemia is worthy of mention.[1]

The so-called convective methods, in which hot air or hot water is employed, are also essentially *conductive heating, as are radiant energy* sources in which the far infra red range (wavelengths of greater than 1,500 millimicrons) is employed. With radiant energy in the near infra-red zone, slightly deeper heating may result, since some of the energy is transmitted through the skin to the subcutaneous levels, where it is absorbed more efficiently.

In all of these methods, heating is relatively slow and, consequently, any real change in temperature can be achieved only after a period of time. Depth heating is produced only by slow conduction of heat from the surface to the deeper tissue layers.

None of these methods are really safe when used on patients suffering from impaired circulation. Ischemic limbs do not tolerate high temperatures. Heat cradles with thermostatically controlled temperatures of 85 to 90 F. have been advocated, but even here tissue metabolism may be accelerated to a level with which the damaged vascular bed cannot always cope and injury may result. Vasodilatation can be produced by indirect means in an extremity without greatly accelerating metabolism, that is, reflex vasodilatation produced *when some* other extremity or part of the body is heated. Intact sympathetic innervation of the part is necessary for this mode of heat therapy to be effective. Direct application of heat when there is obstruction of venous circulation is also dangerous. Here the arterial pathways can supply the demand for additional blood, but the poor venous return does not allow for efficient cooling and dissipation of heat, and, consequently, not only may the tissues be heated to an undesirably high level but considerable edema may develop.

The most efficient methods of heating the deep tissue occur as a consequence of the conversion of high frequency electrical currents into heat. To be most effective, this conversion must take place in the vascular tissues, where body heat is usually being produced. The high frequency currents used are alternating currents having frequencies greater than those frequencies which elicit a neuromuscular response. The term "short wave diathermy" is somewhat misleading, since it suggests that the patient is treated with radiation, whereas, in actuality, the patient is made part of a high frequency circuit. These currents can be applied so as to produce actual destruction of tissue. Only those applications which produce no visible destruction of tissue are considered medical. However, rises in temperature can be obtained which, while resulting in no visible destruction, do produce functional impairment, as manifested by aggravation of pain, increase in edema and other symptoms of overheating. Obviously, it is important to be able to treat in such a manner as to prevent the occurrence of these secondary effects.

The development of heat in tissues by short wave diathermy can be accomplished with either a condenser field or an induction field. Wavelength plays a less important role in heating than the power output of the apparatus, the energy delivered to the patient and the technic employed. For employment of the condenser field, three types of applicators are available: (*a*) the pad electrode, which is not effective for deep heating, producing only superficial effects, and, therefore, is not recommended, (*b*) the cuff electrode, which does not have universal application; hence, hot spots and some excessive surface heating are likely to develop, and (*c*) the air-spaced electrode, the best of the three. Since this method of heating depends on the specific conductivity of the electrolyte in the field, a certain amount of differential heating is bound to result. It has been shown that in the condenser field the power absorption is greater in fat than in other tissues, and, consequently, overheating can result. Fortunately, the efficiency of the blood stream in dissipating heat is such that there is a tendency to equalize temperatures throughout the area and so prevent such specific heating.

The heating of tissue by the use of induction is preferable, since it has more desirable heating characteristics, it is more adaptable to the anatomic configurations and power input into the tissues can be achieved more effectively. This field generates heat in an electrolyte in direct proportion to the conductivity of the electrolyte; it produces heat dominantly in vascular tissue where *it is normally produced, and it exhibits* little specific differential heating.

The intensity of the magnetic field within the coil is at a maximum immediately adjacent to the coil. Therefore, if the coil is wrapped snugly around the part

[1] Martin, G. M.; Roth, G. M.; Elkins, E. C., and Krusen, F. H.: Arch. Phys. Med. **27**: 665, 1946.

treated, heating will be produced faster in the tissues closer to the coil than in the deeper tissues. This will lead to excessive heating of the skin, which must be avoided. In order to produce more heat in the deep tissue, spacing between coil and tissue must be provided. A layer of absorbent toweling, approximately 10 per cent of the diameter of the coil, is adequate and assures the maximum ratio of depth dose to skin dose. It is important in this respect to recall that a reduction in the flow of blood of around 10 per cent can result from the application of pressure to the limbs of as little as 10 mm. of mercury.[2] Careful application of apparatus is necessary to prevent this effect.

Under ordinary conditions of application of heat, vasodilatation may be brought about through the axon reflex mechanism as a consequence of thermal stimulation of sensory receptors. However, heat may also stimulate other cutaneous receptors which reflexly induce vasoconstriction and reduction of the flow of blood. The possibility that one or the other of these antagonistic factors may become dominant must be kept in mind. Results in recent experimental work on the rate of the flow of blood in animals being treated with short wave diathermy make it necessary that previous impressions of the mechanism of deep heating be carefully reviewed. In one set of experiments, Mart and Miller[3] measured the rate of the flow of blood through the coronary vessels before, during and after short wave diathermy over the heart and observed no significant changes in the flow of blood. Subsequently, a group of investigators at Iowa State Medical School[4] treated the hind limbs of dogs with diathermy and observed the femoral arterial inflow into the limb to be reduced. They extended this study to a comparison of denervated and nondenervated limbs and noted similar reductions, with slightly higher rises in temperature in denervated limbs. These results suggest that a portion of the deep-heating effects of short wave diathermy are a consequence of reduced flow of blood through heated tissues. Is this reduced flow a primary or a secondary effect?

It is well known that a rise in tissue temperature will increase local circulation, raise capillary pressure and increase tissue fluid exchange and lymphatic drainage. However, if for any cause tissue fluid accumulates, the resultant pressure on the venous channels will interfere with general circulation. The presence of frank edema may not be necessary for this effect to be produced, since edema is not necessarily detected until a collection of approximately 8 milliliters of fluid per hundred cubic centimeters of tissue has occurred.[5] Such a situation is not without parallel, since the possible presence of low grade edema has been suggested to account for the poor results following local short wave diathermy in patients suffering from chronic arthritis.

The decided increase in implantation of metals by surgical means has revived discussion of the potential dangers of short wave therapy in the postoperative treatment of patients who have had operations of this type. Presumably, injury to the tissues contiguous to the metal would result because of distortion or concentration of the short wave field at the implant. This problem has been investigated recently by two groups of investigators.[6] In general, it appears that, if circulation is not impaired, short wave diathermy, with the usual precautions, can be safely applied to areas where surgical metals are situated in the deep tissues. However, caution must still be exercised, since overheating of tissues may occur around metallic parts located on or near the surface.

The subject of short wave diathermy cannot be closed without a consideration of dosage. At the present time there is no simple method of estimating the amount of energy absorbed by any single patient. As a consequence, dependence is placed on the most empiric procedure possible, that of using the patient's skin tolerance as the guide to the final dosage to be employed. In patients with impaired thermal sense or with peripheral vascular disease, burns may result. This is of special importance in aged patients, who frequently have lessened cutaneous sensibility.

During the past ten to fifteen years, there has been an active search, particularly by Dr. Frank H. Krusen of the Mayo Clinic, for sources of electromagnetic waves with much shorter lengths than those now commonly employed in so-called short wave diathermy. In the latter method, wavelengths of 21.95, 10.98 and 7.32 M. are available in contrast to the newest band of 12 cm. or 2,400 to 2,500 megacycles per second now allocated to physical medicine by the Federal Communications Commission. Radio frequency wavelengths of a few centimeters have a number of interesting properties which might make them of particular value in this field of specialization. Microwaves, so-called, have optical properties. They can be reflected, refracted and diffracted. They can be focused with a suitable metal lens into sharp beams. Furthermore, they may be selectively absorbed. A new field of research, called "microwave spectroscopy," gives promise of furnishing valuable information on molecular structure. Oxygen and water molecules (in gaseous form) absorb particular microwave frequencies. Whether or not the various biologic mediums will absorb microwaves selectively is not yet known. It has been shown that penetration of fat is only slightly less favorable than penetration in muscle tissue.[7] This is in contrast to the greater absorption by fat of 11 M. energy. No toweling is needed for spacing, and the subject is not tied down to the apparatus, as with short wave diathermy.

Most physicians have heard of the employment of microwaves in "radar," in which short radio frequency waves are discharged in bursts as a pulse-echo system. This type of energy is not feasible for therapeutic purposes, and continuously emitted energy is preferred. A cavity magnetron which generates continuous waves is now available. An indication of the potential superiority of waves of 12 cm. for therapeutic purposes is pointed out in a report from the Radiation Laboratory at the Massachusetts Institute of Technology. It was observed that the absorption factor of water at 100 F.

for microwaves having a frequency of 2.450 megacycles per second was approximately seven thousand times that for radio waves having a frequency of 27 megacycles per second. The latter frequency is commonly used in short wave diathermy.

Studies have just been begun on evaluation of the usefulness of centimeter waves. Several authors have reported that exposure to radar radiations has no effect on personnel.[8] Since these investigations were concerned with exposure to radar pulses—brief, rapid bursts of energy—they were of value only in dispelling fears of radar personnel regarding possible injury. Results of exposure to continuous microwave energy have just recently been presented in a preliminary report by Krusen and his associates.[9] Although they used equipment which produced continuous microwave energy at a frequency of 3,000 megacycles per second (10 cm.) and used only a single type of applicator, the general conclusions they have made will in all probability be applicable to a wave of 12 cm.

A number of investigators, such as Hollmann in Germany[10] and Hemingway and Stenstrom in this country[11] have theoretically discussed the use of centimeter wavelengths from the standpoint that they could be focused so as to cause heating of deep tissues without excessive heating of the skin. Krusen and his associates[9] have now shown that temperature of deep tissue can be raised by microwaves. Measurements were made of cutaneous, subcutaneous, superficial muscle and deep muscle temperatures following application of microwave energy. Unfortunately, as was the case in studying the effects of the usual short wave diathermy technic, it was impossible to measure temperatures during exposure to the high frequency field. An energy output of approximately 65 watts for a period of twenty minutes raised cutaneous, subcutaneous and muscle temperatures an average of 3 to 5 degrees Centigrade. This means that even with similar rises in temperature of all tissues, the final temperature of deep tissue is higher than that of subcutaneous or cutaneous tissue. Furthermore, the rate and degree of cooling is always more rapid in superficial tissues than in deeper ones. The flow of blood, as measured in the femoral vein, was approximately doubled as a consequence of the treatment. This is in sharp contrast to the results previously mentioned, wherein reductions in the flow of blood were observed following short wave diathermy. Although extension to human beings of the results obtained from experiments with animals is always dangerous, heating with microwaves offers promise of considerable usefulness in the practice of physical medicine. Experimentation in progress will permit reports at a later date regarding the clinical applications of this new tool.

The effects of heat on human beings are complex, and it is impossible in the present state of knowledge to do more than suggest the potentialities of heat therapy. Extension of knowledge will continue with the continued development of the scientific approach to physical medicine.

There is another mode of treatment available to general practitioners that has not had such extensive exploitation as the use of heat. The introduction or exchange of ions by means of the direct current within the tissues has not been popular in this country, but has been extensively employed in Europe, especially by the French.[12] Iontophoresis may have wide potential application in general practice.

The introduction of medicaments into the body by common ion transfer has distinct theoretic limitations. The low velocity of the ions and the low potential at which they are introduced precludes penetration deeper than the superficial layers of the skin. Furthermore, the quantity of any drug that can be introduced is certainly infinitesimal. Yet, despite these limitations, both local and systemic responses have been obtained.

The systemic response is probably due to diffusion of the drug into the circulating blood. A number of foreign investigators have expressed the belief that the physical characteristics of the current produce an effect on the colloids of the organism and so may account for some of the beneficial effects of iontophoresis.

Over thirty different anions and cations have been employed to treat as large a number of clinical entities. With some ions local effects predominate, as in the case of cocaine, which produces anesthesia and edema of the skin primarily at the electrodes; with others, systemic effects appear before any local reaction occurs, as in the case of strychnine, and in still others, such as histamine, "mecholyl chloride" (acetyl-β-methylcholine chloride) and epinephrine, both local and systemic reactions can be produced. Common ion transfer of the salts of the metals appears, on the best of available evidence, to have primarily local effects.

Iontophoresis has been employed with apparent advantage in a number of peripheral vascular disorders and dermatologic conditions. Iontophoresis with "mecholyl chloride" or histamine produces relief from pain, swelling and stiffness, but does not increase function of the joints, strength of muscle or relief from fatigue. The main positive effects are in superficial dilatation of the capillary bed, with resultant intensive hyperemia. Copper has been used effectively in treatment of so-called "athlete's foot." Unfortunately, there is no completely satisfactory scientific evaluation of the efficacy of "common ion transfer," and the enthusiastic clinical reports have, in general, not been supported by statistical evidence. This mode of treatment has been of value in selected cases, but until more is known of the basic mechanism, this method cannot be considered to have broad general application to clinical conditions.

COMMENT

It was not my purpose in this paper to either praise or decry any mode of treatment, but to bring to attention the need for objective evaluation of the tools of physical medicine. It is gratifying not only to observe the progress that has been made in this respect but also to note the development of teams of trained investigators who are attacking the fundamental problems of physical medicine. It is only through the unequivocal establishment of the principles underlying the practice of physical medicine that treatment can be properly prescribed and the patient's progress adequately evaluated.

EXPERIENCES WITH TETRAETHYLAMMONIUM CHLORIDE IN HYPERTENSION

Tetraethylammonium chloride is a quaternary ammonium compound which blocks the transmission of nervous impulses across autonomic ganglions. Acheson and Moe[1] first demonstrated this ganglionic site of action in dogs and cats, using as test responses the reactions of the blood pressure, heart rate and nictitating membrane. They demonstrated that when the compound is injected intravenously it produces a prompt fall in arterial pressure in animals in which the arterial pressure is elevated from the increase in sympathetic tone of barbiturate anesthesia. After section of the cervical cord in such animals the sympathetic tone is abolished, and the drug then fails to produce further change in pressure. With restoration of the pressure and vascular tone by stimulation of the distal segment of the sectioned cervical cord the administration of the drug again produces a fall in pressure to the same level as that found in the absence of sympathetic tone. Acheson and Moe also demonstrated that there is no local action of the drug on blood vessels since intra-arterial injection fails to produce changes in blood flow. The drug does not prevent the vasopressor activity of epinephrine or angiotonin, which act directly on the arterioles, so that hypertension induced by large infusions of such substances is not altered in the experimental animal.[2]

EFFECT OF AUTONOMIC NERVOUS SYSTEM BLOCKADE IN MAN

In man a similar ganglionic blockade of both the parasympathetic and sympathetic nervous systems may be produced by the intravenous or intramuscular injections of tetraethylammonium chloride.[3] The effects of such a blockade have already been described,[4] and consist principally of decrease in blood pressure, with the development of postural hypotension, tachycardia, increase in blood flow in the extremities resulting in a rise in cutaneous temperature,[5] cessation of sweating, a dry mouth, cessation of gastrointestinal movement and a decrease in gastric secretion,[6] loss of bladder tone,[7] loss of ocular accommodation with partial pupillary dilatation and occasionally ptosis of the eyelids.

DOSE OF TETRAETHYLAMMONIUM CHLORIDE IN MAN

The decrease in blood pressure is usually rather transient following an intravenous injection, and the duration of the effect is dependent in part on the amount administered. In order to obtain measurable dilatation of the peripheral vascular bed, 500 mg. of the drug should be administered intravenously. The effects of smaller doses may not be as complete. In general, 300 to 500 mg. (6 to 10 mg. per kilogram of body weight) has been injected intravenously in the studies of the change in blood pressure and at least 500 mg. (between 7 and 10 mg. per kilogram of body weight) in the studies of the changes in peripheral blood flow. The intramuscular dose should probably not exceed 20 mg. per kilogram of body weight. Oral administration is not satisfactory because of poor absorption from the gastrointestinal tract.

MECHANISM OF THE FALL IN ARTERIAL PRESSURE WITH TETRAETHYLAMMONIUM CHLORIDE

Arterial pressure is dependent on the volume of blood in the arterial system and the character of the volume elasticity of the arterial walls. The volume of blood in the arteries is dependent on the cardiac output, which is a function of the heart rate and stroke volume, as well as the rate of flow out of the arterial system through the arterioles. Small changes in the cardiac output will produce relatively little change in the arterial pressure because of the compensatory influence of the reflex sympathetic vasoconstrictor tone.

The rate of flow out of the arterial system at a given head of pressure is dependent on the degree of dilatation or constriction of the arterioles. This is controlled normally by reflex sympathetic vasoconstrictor tone but may also be affected by structural changes in the walls of the vessels and by humoral substances, such as epinephrine or angiotonin, acting directly on them. The decrease in arterial pressure usually noted after injections of tetraethylammonium chloride must be explained either as a result of a diminution of cardiac output or a decrease in sympathetic vasoconstrictor tone resulting in a greater outflow of blood from the arteries. It has been found that after the administration of the drug there is either no change in cardiac output or more commonly an increase in the output in both normal and hypertensive subjects probably associated with the increase in heart rate from the parasympathetic blockade.[8] Therefore, in the presence of an augmented cardiac output, the fall in arterial pressure must be explained on the basis of an increased outflow of blood from the arteries because of the diminution in arteriolar constriction controlled by the sympathetic nervous system. The extent of the fall in arterial pressure at a given initial pressure must therefore reflect in part the role of the sympathetic

vasoconstrictor tone in the maintenance of the pressure at that level. On the other hand, if the same degree of arteriolar dilatation occurred at different pressure levels, a greater decrease in pressure might be expected in the arteries under the higher initial pressure and therefore would not necessarily indicate that these vessels were under a greater sympathetic tone.

It is unjustified to assume, however, that the decrease in pressure noted after injections of tetraethylammonium chloride will give an absolute measurement of the role of reflex vasoconstriction in maintaining the level of the arterial pressure. The change in heart rate, if great, may tend to prevent as pronounced a fall in diastolic pressure as might be experienced from vasodilatation alone. It is probable, however, that the change in the cardiac output resulting from the tachycardia or the tachycardia itself are minor factors in altering the arterial pressure in the majority of the cases, for the average increase in rate is only 19 beats per minute.

In animal experiments the drug appears to produce a complete blockade of reflex vasoconstrictor tone. Observations on peripheral blood flow in man would suggest that in the doses used the blockade is not complete. There is a somewhat greater increase in peripheral blood flow in the feet after lumbar paravertebral block than after injection of tetraethylammonium chloride.[5]

While these limitations are recognized, they do not prevent the use of the drug in the evaluation of the role of sympathetic vasoconstrictor tone in the maintenance of arterial pressure. It is likely that in most instances changes in the diastolic pressure will parallel the changes in sympathetic tone produced by the drug.

THE EXTENT OF FALL IN BLOOD PRESSURE

A study of the role of the reflex sympathetic vasoconstrictor tone in the maintenance of arterial pressure at different initial levels of pressure has been made on 437 patients. The drug has been administered intravenously in doses of 300 to 500 mg. to patients in whom determinations of blood pressure were made for several minutes before the injection and continued every thirty to sixty seconds after the injection for fifteen to thirty minutes. In general the pressure is diminished in the majority of the cases and remains depressed for five to fifteen minutes. Evidence of diminished sympathetic tone may be present for twenty to forty minutes after an injection. Postural hypotension and increased peripheral blood flow persist after the arterial pressure has returned to its initial level. With the tachycardia resulting from diminished vagal tone there is a somewhat greater fall in the systolic pressure than in the diastolic pressure. Changes in the diastolic pressure, therefore, have been used to indicate the alterations in the level of the pressure produced as a result of the drug.

The extent of the decrease in pressure is largely dependent on the initial elevation of pressure (chart 1). Normal subjects with low initial diastolic pressures uncommonly experience a significant decrease in pressure after injection of the drug. In fact, there is in some subjects a slight rise in diastolic pressure. Thirty-five per cent of 82 persons with initial diastolic pressures below 80 had no change or a slight increase in diastolic pressure after receiving tetraethylammonium chloride. These were in general healthy subjects who were volunteers for the observations. Between 40 and 50 per cent of the patients studied with normal initial diastolic pressures failed to have a fall in pressure of as much as 10 per cent of the initial level. It would seem likely that in this group sympathetic vasoconstrictor tone played only a small role in the maintenance of arterial pressure. Seventeen patients with low diastolic pressures, however, experienced a 20 per cent or greater decrease in pressure. With few exceptions these were patients with hyperreactive vascular responses or other vascular abnormalities and might be thought to have a greater degree of vasoconstrictor tone.

Of the 91 patients with initial diastolic pressures between 90 and 109 mm. of mercury there was a greater average fall in pressure after administration of tetraethylammonium chloride. Only 24 per cent of the patients failed to have at least a 10 per cent decrease in diastolic pressure.

In the 228 hypertensive patients with initial diastolic pressures above 110, the drug produced progressively greater mean decreases in pressure with higher initial diastolic pressures. Only 16 per cent of these persons failed to have more than a 10 per cent decrease in pressure after the injection. It would seem likely that in these patients the blood pressure was maintained with less reflex sympathetic vasoconstrictor tone than in those patients who had greater decreases in pressure. On examination of the clinical records of the 37 patients, local angiospasm of the retinal vessels was less commonly found; there was a greater incidence of retinal arteriosclerosis, cardiac enlargement and impaired renal excretory function or nephritis than in the group that had larger decreases in pressure.

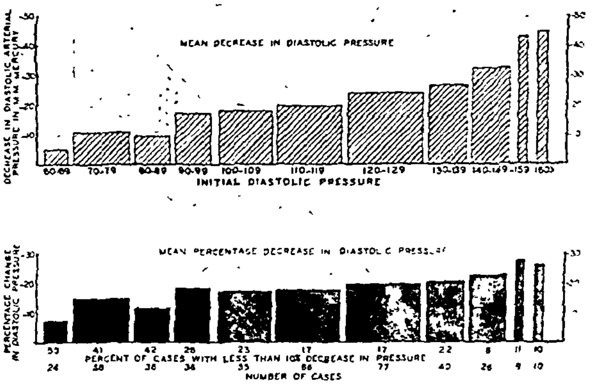

Chart 1.—Mean decrease in diastolic pressure in millimeters of mercury experienced in 437 patients who received 300 to 500 mg. of tetraethylammonium chloride intravenously. The width of each column expresses the number of cases arranged in groups according to the initial diastolic pressure. The lower solid black columns represent the mean percentage change from the initial diastolic pressure after administration of tetraethylammonium chloride.

It is apparent from chart 1 that the blockade of sympathetic tone produced by the drug resulted in progressively greater mean decreases in diastolic pressure from a 4 mm. fall at an initial diastolic pressure between 60 and 69 to a 44 mm. fall when the initial pressure was above 160 mm. of mercury. The average percentage change in diastolic pressure is greater at pressures above 90 and increases slightly but progressively at higher levels. This suggests that there is some increase in sympathetic tone in the hypertensive state, but it is not proportionately much greater at higher pressure levels. There were, however, large individual variations in the response to the drug which would suggest that in some patients the sympathetic vasoconstrictor tone was of more importance in maintaining the pressure, while in others it played a small role and the elevated pressure was maintained by other causes. In a small number of patients with high diastolic pressures, the fall in pressure was so great that it was followed by a momentary state of collapse and the clinical appearance suggestive of cerebral anoxia. A 300 to 500 mg. injection of tetraethylammonium chloride may be dangerous in patients with a diastolic pressure over 150.

Some degree of hypertension persisted after the fall of arterial pressure produced by the administration of tetraethylammonium chloride, even though sympathetic tone was decreased (chart 2). This would suggest that other factors such as arteriolar sclerosis, endocrine or humoral mechanisms were also important in the maintenance of an elevated diastolic pressure. It is apparent that in a consideration of the mean pressure changes at different diastolic levels the diminution of sympathetic tone produced in this manner may bring about greater decreases in pressure at higher diastolic levels but cannot be expected to produce a fall in pressure to normal.

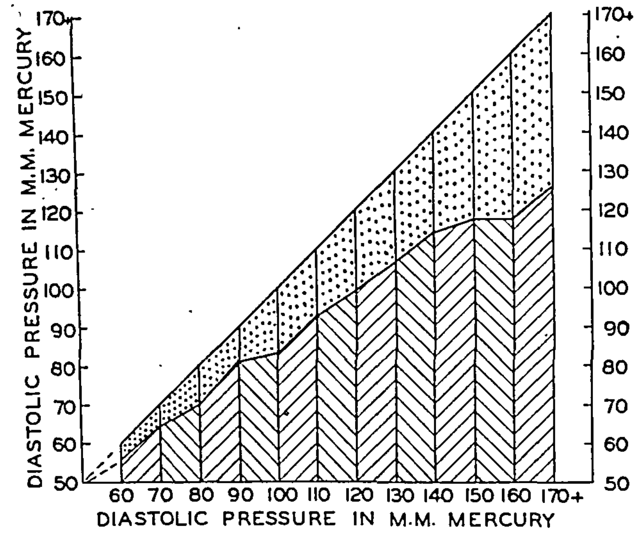

Chart 2.—The stippled area represents the mean decrease in pressure in millimeters of mercury at each diastolic level produced by 300 to 500 mg. of tetraethylammonium chloride intravenously in 437 patients. The decrease in pressure is greater at higher initial pressures. The role of reflex sympathetic tone in the maintenance of pressure at different pressure levels will be reflected by the stippled area. Hypertension may still be present, however, after the decrease in sympathetic tone following *administration of tetraethylammonium chloride.*

This is similar to the experience found after splanchnicectomy for hypertension. The operation also decreases the extent of the sympathetic vasoconstrictor tone, but it does not commonly produce a fall in pressure to normal. In the patients with high diastolic pressures greater decreases in pressure are experienced than in those with lower diastolic pressure, but usually some degree of hypertension will persist after the operation.

FAILURE TO EXPERIENCE A DECREASE IN PRESSURE

It has been noted that certain patients who are apprehensive about the procedure of multiple blood pressure measurements and intravenous injections may fail to respond to tetraethylammonium chloride on that occasion but respond later to an intramuscular injection or to the same procedure on another occasion when they are no longer apprehensive. It has been shown in animals[2] that hypertension produced by the infusion of epinephrine or angiotonin may not be altered by tetraethylammonium chloride. It seems likely that these patients may have epinephrine-like substances present at the time of injection which will alter the effects of tetraethylammonium chloride by the direct action of the pressor substance on the arterioles.

Other patients who are not apprehensive may fail to have a significant decrease in pressure after repeated injections of the drug though they may have an increase in peripheral blood flow, postural hypotension and other manifestations of alteration in the degree of sympathetic tone. It would seem likely that the recumbent blood pressure in such cases is maintained without the aid of sympathetic vasoconstrictor tone.

In a few subjects there is an increase in heart rate of 40 to 50 beats per minute with a resulting tachycardia of 140 to 150. In some patients with such a rapid rate there may still be a fall in diastolic pressure; in others, however, it is possible that diastole is too short to permit the usual fall in diastolic pressure.

In 6 patients with repeated injections, there was a change in the response of the blood pressure to the drug. The patient would have a moderate decrease in pressure with the initial injection or the first two or three injections, but with subsequent injections the diastolic pressure failed to change even though other evidence of blockade could be demonstrated. There is no satisfactory explanation for this at present.

EVALUATION OF SYMPATHETIC TONE IN THE SELECTION OF CASES FOR OPERATION

It is unlikely that patients with hypertension maintained with a low degree of sympathetic vasoconstrictor tone will be greatly aided by operative procedures designed to interrupt the sympathetic control of vessels. Evaluation of this functional type of vasoconstriction is difficult and in general unreliable. Various types of pressor and depressor responses have been utilized as a test of the variability of blood pressure in order to better select candidates for the successful operative treatment of hypertension. No test has been satisfactory.

Because of the action of tetraethylammonium chloride in producing an autonomic blockade, it would seem to be a better method of evaluating the changes in pressure that could be expected by operative procedures. On consideration of the effects of the drug on the circulation, it is obvious that it will not simulate precisely the circulatory changes to be found in the absence of sympathetic tone alone. It may be a useful adjunct, however, in roughly estimating the extent of the reflex vasoconstrictor tone in the selection of candidates who may be improved by operative procedures on the sympathetic nervous system.

To evaluate this type of depressor response, candidates otherwise suitable for splanchnicectomy have been given injections of 300 to 500 mg. of tetraethyl ammonium chloride intravenously, and the ensuing alteration in the blood pressure has been carefully noted. In the performance of the test, excitement and alarm on the part of the patient is avoided or the test is repeated on another occasion. The response was evaluated by the percentage change between the initial diastolic pressure and the lowest diastolic pressure obtained over a three minute period after the injection of the drug.

At present, 58 patients who received injections of tetraethylammonium chloride in these doses have been reexamined six to eighteen months (average one year) after supradiaphragmatic splanchnicectomy and lower dorsal ganglionectomy (Peet). The depressor response to tetraethylammonium chloride was not considered in accepting or rejecting suitable candidates for the operation. Ten patients were studied in a similar manner early in our experience but were given small intravenous doses or intramuscular injections and are not included because of the uncertainty of a standard reaction pattern.

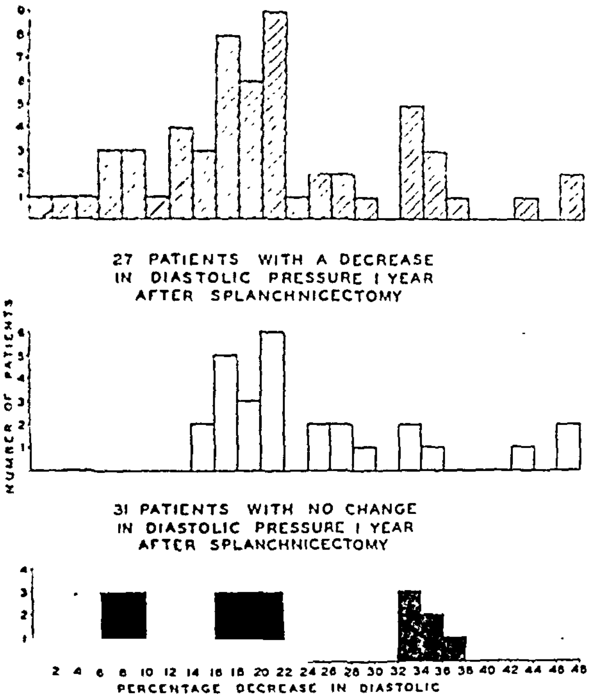

Chart 3.—The percentage decrease in diastolic pressure produced by 300 to 500 mg. of tetraethylammonium chloride intravenously before operation in 58 patients who have been followed for an average of one year after splanchnicectomy.

The 58 patients have been divided into those in whom a decrease in blood pressure of more than 10 per cent of the initial diastolic pressure was noted one year after the operation, 27 patients, and those who had even less change in pressure or an increase in pressure after operation, 31 patients.

It is noted in chart 3 that all patients who had a decrease in pressure after operation had a considerable change in the preoperative diastolic pressure after the administration of tetraethylammonium chloride. The smallest change in diastolic pressure after administration of the drug was 14 per cent of the initial diastolic level.

In contrast to this were the 31 patients who had no change in diastolic pressure after operation. Ten of the 31 failed to have even a 10 per cent change in their preoperative diastolic pressure after receiving tetraethylammonium chloride. Four more had less than 14 per cent decrease in pressure. The other 17 patients, however, had responses similar to the responses of those who had improved after the operation. It would seem probable that the patients who failed to have a decrease in diastolic pressure of 10 per cent or more after injections of tetraethylammonium chloride might not be expected to have as good an effect from the operative procedure. Final conclusions, however, should not be made from such a small series of cases. As the series is extended, it is probable that some patients who were alarmed or excited at the time of the injection will fail to respond to the drug, but may nonetheless have a good result from the operation. A good response to the drug, on the other hand, does not necessarily indicate that a successful result from splanchnicetomy can be expected. The chances of a successful result are somewhat better.

RESPONSE OF THE BLOOD PRESSURE AFTER SPLANCHNICECTOMY

If the sympathetic vasoconstrictor tone in the splanchnic area was important in the maintenance of blood pressure in the supine position, it would seem likely that the extent of the fall in diastolic pressure with tetraethylammonium chloride after section of these nerves would be diminished. This was observed in the patients who had experienced some fall in pressure one year after the operation. Before operation there was a mean decrease in diastolic pressure of 24 per cent in response to the drug, while after operation there was an average decrease of only 9.6 per cent (chart 4). There was a somewhat better than average response to the drug before operation and a decidedly poorer than average response after operation. In these cases it would appear likely that the sympathetic tone in the splanchnic bed had contributed significantly to the maintenance of the increased arterial pressure.

On the other hand, the patients who failed to have any change in pressure after the operation in general had an average preoperative response to tetraethylammonium chloride somewhat below the average levels found in the study of the 437 patients. The preoperative and postoperative decrease in diastolic pressure with the drug averaged 17.5 and 15.8 per cent, respectively. It is possible in these patients that the splanchnic vascular bed did not contribute significantly to the increased peripheral vascular resistance, since dener-

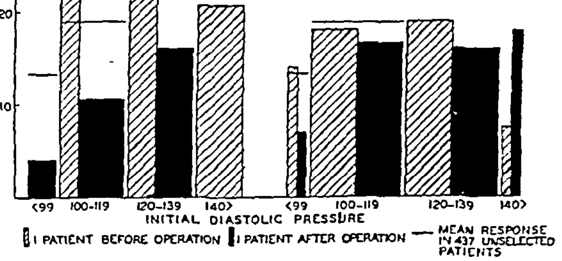

Chart 4.—A comparison of the difference in response of the diastolic pressure to tetraethylammonium chloride before and one year after splanchnicectomy. The shaded columns represent the mean percentage decrease in diastolic pressure following administration of tetraethylammonium chloride before operation. The solid black columns represent the mean decrease in diastolic pressure following administration of tetraethylammonium chloride one year after operation.

vation of this area neither lowered the pressure nor significantly affected the response to a generalized decrease in sympathetic tone.

EFFECT OF TETRAETHYLAMMONIUM CHLORIDE ON HEADACHE

In addition to being of some value in the rejection of cases in which a good result after splanchnicectomy was less likely there has been a rather remarkable relief of symptoms in some hypertensive patients following injection of the drug. In a number of instances hypertensive patients who entered the hospital with severe headaches, somewhat confused thought and at times blurring of vision had prompt symptomatic relief following the administration of the drug. In some the headache would recur a few hours later, while in others it would not return for many weeks. It is always difficult to evaluate such subjective responses even though in many instances control injections of isotonic solution of sodium chloride were administered to rule out suggestive relief of symptoms.

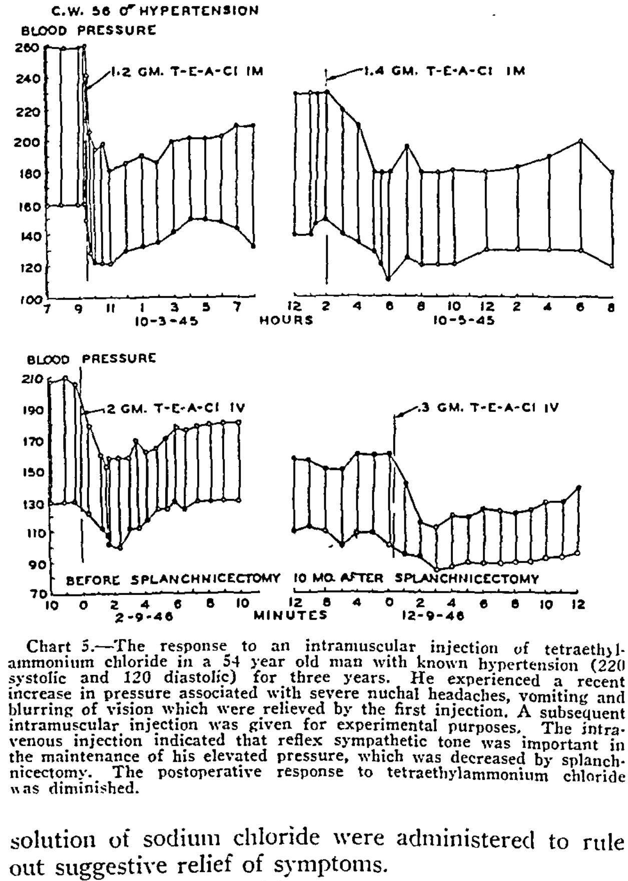

Chart 5.—The response to an intramuscular injection of tetraethylammonium chloride in a 54 year old man with known hypertension (220 systolic and 120 diastolic) for three years. He experienced a recent increase in pressure associated with severe nuchal headaches, vomiting and blurring of vision which were relieved by the first injection. A subsequent intramuscular injection was given for experimental purposes. The intravenous injection indicated that reflex sympathetic tone was important in the maintenance of his elevated pressure, which was decreased by splanchnicectomy. The postoperative response to tetraethylammonium chloride was diminished.

In those patients with hypertension and uremia no symptomatic relief was noted, and in general the drug had little effect. In cases of dyspnea associated with uremia and hypertensive heart failure, the administration of the drug generally failed to lower the pressure significantly and only made the patient more uncomfortable because of the presence of postural hypotension. A few patients with heart failure without uremia experienced temporary relief of dyspnea during the depression of the blood pressure.

INTRAMUSCULAR INJECTIONS

When the drug was administered in the muscle in doses between 10 and 20 mg. per kilogram of body weight, the effects were generally less predictable but more prolonged because of different rates of absorption. In some instances there was an abrupt drop in pressure within two and three minutes which would continue for one to five hours (chart 5). At other times no change in pressure occurred in patients who had experienced a considerable decrease after an intravenous dose. In general, the intramuscular injection was associated with moderate local pain at the site of the injection. The other effects of autonomic blockade make the patient rather uncomfortable. Except for the occasional relief of severe symptoms resulting from the hypertension, the patient generally fails to be benefited by a prolonged period of depressed pressure, for as the effects of the drug disappear the pressure returns to its previous level.

Occasionally in hypertensive patients who have had recent elevation of pressure above their usual pressure level, either intravenous or intramuscular injections may decrease the pressure considerably. As the effects of the drug disappear the pressure will return to its usual level rather than to the high level temporarily present (chart 5). Similar changes have frequently been observed to occur spontaneously after one to three days of hospitalization.

THE FUTURE OF SIMILAR DRUGS IN HYPERTENSION

The action of compounds of this type apparently depends on their ability to compete temporarily with acetylcholine at the ganglionic junction of both the parasympathetic and sympathetic nervous systems. Acetylcholine is necessary for the transmission of nerve impulses through those ganglions. It would seem likely, therefore, that other drugs of this type which would be developed would have the same type of action on both the sympathetic and parasympathetic nervous systems if they produce a blockade at the ganglions. Under these circumstances prolongation of the action of the blockade will generally result in discomfort to the patient from the absence of parasympathetic tone on the gastrointestinal tract and salivary glands. The continued postural hypotension from sympathetic ganglionic blockade forces the patient to remain supine. The loss of accommodation is annoying. Methods of prolonging the action of tetraethylammonium chloride have been investigated without success up to the present time. Even if the effects could be more prolonged such drugs would offer no advantages in the daily management of the hypertensive patient. They may have limited usefulness in the evaluation of vasomotor tone and in the symptomatic relief of hypertensive headaches. Tetraethylammonium chloride is, however, a useful pharmacologic tool in the study of the manifestations of the autonomic nervous system.

SUMMARY

The action of tetraethylammonium chloride on the blood pressure of 437 patients has been described.

It is suggested from the mean decreases in blood pressure that an abnormally elevated initial diastolic pressure is maintained with somewhat more reflex vasoconstrictor tone than when the initial diastolic pressure is normal. Decrease in sympathetic tone produced by the drug fails to return the pressure to normal, suggesting that other factors are present in maintaining the elevated pressure.

Failure of the pressure to fall more than 10 per cent of the initial diastolic level was noted in 16 per cent of 228 hypertensive patients. These patients had a

greater incidence of degenerative changes associated with their hypertension. It is suggested that vasomotor tone did not play an important role in the maintenance of pressure in these cases.

All 27 patients who had some decrease in diastolic pressure one year after splanchnicectomy responded to the drug before operation with a fall in pressure greater than 14 per cent of the initial level. Ten of the 31 patients who failed to have a change in pressure with splanchnicectomy had less than a 10 per cent fall in pressure with the drug. The response to repeated injections of the drug one year after splanchnicectomy was greatly decreased in the patients who had had a fall in pressure with operation and was essentially unchanged in those patients who failed to have a decrease in pressure with operation.

Hypertensive headaches are often relieved by the drug.

Tetraethylammonium chloride has no place in the daily management of hypertension.

ABSTRACT OF DISCUSSION

Dr. K. G. Kohlstaedt, Indianapolis: Dr. Lyons has noted a decrease in the hypotensive effect of tetraethylammonium in patients in whom the blood pressure was significantly reduced by sympathectomy. A comparable loss of responsiveness to the drug was not observed in persons in whom surgical treatment had failed to alter the level of the arterial pressure. These results suggest that in some but not all hypertensive persons vasoconstrictor tone in the splanchnic area may be a factor in maintaining an elevated arterial pressure in the supine position. However, we must be cautious in drawing conclusions regarding the etiology of hypertension on the basis of the patient's response to any drug. Interpretation of Dr. Lyons' results is complicated because tetraethylammonium affects both the sympathetic and the parasympathetic nervous system. Hypertension is a clinical sign, not a disease entity, and more than one causative agent may be responsible for elevating the arterial pressure in the syndrome which we call essential hypertension. We cannot expect widespread blockade of the autonomic ganglions to produce the same effects as the removal of a portion of the sympathetic nervous system. In my opinion the failure of tetraethylammonium chloride to lower distolic pressure as much as 15 per cent is more significant than any hypotensive effect which the drug may have. In Dr. Lyons' cases, there were 14 in which tetraethylammonium did not lower the diastolic pressure, and in all of these sympathectomy also failed to produce a permanent reduction in arterial pressure. Investigation of the renal hemodynamics by means of iodopyracet-inulin clearance has revealed that in essential hypertension an increase in filtration fraction (the ratio of glomerular filtration-inulin clearance to the effective renal plasma flow-iodopyracet clearance) indicates an advanced stage of the disease. There is a considerable amount of evidence to support the hypothesis that this change in renal hemodynamics is due to the direct action of a pressor substance on the arterioles of the kidney. In patients who did not respond to tetraethylammonium in our group at the Indianapolis City Hospital, there was invariably an elevated filtration fraction. On the other hand, in some with an elevated filtration fraction, tetraethylammonium lowered the diastolic pressure more than 15 per cent, and in all patients with essential hypertension in whom the filtration fraction was normal tetraethylammonium always produced a decrease in diastolic pressure. These findings suggest that failure to respond to tetraethylammonium may denote a type of hypertension in which vasoconstrictor tone may play only a minor role in the production of an elevated arterial pressure.

Dr. Eugene Foldes, New York: I should like to present some observations with reference to the pathogenesis and therapy of hypertension. A patient with hypertension was under observation for thirteen years. In 1936, diabetes was discovered. Before the discovery of diabetes and probably at the time when hyperglycemia developed, the blood pressure dropped and stayed at normal or moderately increased levels for about one year. Later, when the blood sugar was brought under control, the blood pressure increased again. In another patient, a moderate hypertension developed in the course of years. In 1942, diabetes was discovered. As in the first case, the blood pressure dropped, probably simultaneously with the development of hyperglycemia. In the case of diabetes and hypertension represented in this slide, you can see that when the blood sugar rises, the blood pressure drops, and when the blood sugar drops, the blood pressure increases. Broadly speaking, it can be stated that in the hypertensive diabetic patient there is an inverse relation between the blood sugar and the blood pressure. One possible explanation is that hyperglycemia leads to glycosuria, glycosuria leads to polyuria, polyuria to dehydration, dehydration to reduction of the circulatory blood volume and that to a drop in the blood pressure. The other possible explanation considers the adrenal cortex. It is axiomatic that if in the organism such conditions exist as are promoted by a gland of internal secretion, that gland decreases its function. Therefore, if the blood sugar increases in the hypertensive diabetic patient, the adrenal cortex which tends to raise the blood sugar would seem to decrease its function. If the adrenal cortex decreases its function, sodium chloride is eliminated through the kidneys at an increased rate. That would seem to be followed by a reduction of the circulatory blood volume and by a reduction of the blood pressure. Further investigations are necessary. It will also be necessary to determine whether or not hypertensive diabetic patients will be better off with a comparatively high blood sugar in order to keep their blood pressure comparatively low.

Dr. Frederick M. Allen, New York: Whatever the symptomatic or instructive values of any drugs, they should not distract attention from the fundamental diet treatment. Our papers proposing salt-free diet in 1920 and 1922 gave full credit to the prior French work, but our method was complete before we ever knew of the French work. We originated the following major advances: 1. We corrected the fallacy of "chloridemia" and prohibited not only the chloride but all other salts, such as sodium bicarbonate and baking powder. 2. We introduced the necessary standard of strictness, and although laxity of so-called salt-free diets prevailed long afterward, all recent writers on cardiac, renal and vascular treatments now accept our strict standard. 3. Except for the unknown work of de Snoo, we originated salt-free diet for puerperal eclampsia. 4. We insisted on essential hypertension as a definite disease and not an accidental complex of symptoms. 5. We characterized salt-free diet as a specific means of relieving functional strain and therefore as a solution for the huge mortality problem, by arresting progressiveness in cases of disease properly diagnosed and treated from early stages. These ideas were so advanced that not all are yet accepted, though they are supported by twenty-eight years of experience. In experimental animals, the hypertensive influence of salt was demonstrated first by Verney and Vogt in England, then by myself and lately by Grollman-Harrison, Selye and others.

Dr. Richard H. Lyons, Ann Arbor, Mich.: Dr. Kohlstaedt's point is well taken, that if we are to use a negative response to tetraethylammonium to contraindicate sympathectomy then great care must be taken to avoid apprehension and to give adequate doses. It has been shown that injection of epinephrine in animals or man would negate the response to tetraethylammonium, and certainly in human beings who are apprehensive there may be no fall in pressure due to an epinephrine response. I do not wish to enter into the polemics of the causes or specific treatment of hypertension. I have merely tried to describe to you the role that vasomotor tone may play in the maintenance of an elevated blood pressure.

STREPTOMYCIN SENSITIVITY

Development of Sensitivity in Nursing Personnel Through Contact During Administration of the Drug to Patients

SOLOMON M. RAUCHWERGER, M.D.
FREDERICK A. ERSKINE, M.D.
and
WALTER L. NALLS, M.D.
Oteen, N. C.

Although the development of sensitivity to streptomycin is of common occurrence in patients receiving the drug over a period of weeks or months and has been reported many times, we have been unable to find specific reports in the literature concerning the incidence and character of the reaction among personnel concerned with the administration of the drug. In recent protocols issued for administration purposes by the Veterans Administration outlining use of the drug in Veterans Administration hospitals,[1] there is brief mention of 2 cases developing in personnel after prolonged contact. The suggestion was made in these protocols that all nurses be given patch tests to determine sensitivity, apparently with the intent that positive reactors be kept from contact with the drug. Through personal communication [2] it has also been reported that instances of sensitivity to streptomycin have developed among the nursing staff at Western North Carolina Sanatorium. Peck, Siegal and Bergamini [3] stated that 5 per cent of penicillin sensitivity is the result of "autosensitization," occurring in persons who have a dermatomycosis, the fungi present producing penicillin which acts as the antigen. In none of our cases were we able to detect the presence of an actinomycotic infection which might cause similar sensitization to streptomycin.

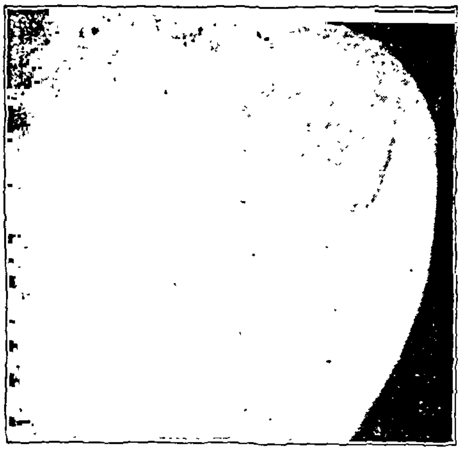

Fig. 1.—Denuded area on thumb of nurse representing a contact dermatitis following development of sensitivity to streptomycin.

Over a period of twenty months streptomycin was administered to 233 patients in the thousand bed tuberculosis hospital at Oteen, N. C. During this time in 6 nurses a definite sensitivity to the drug developed. In view of the widespread use of the drug, especially in tuberculosis sanatoriums, and in view of the acute shortage of nurses throughout the country and the factors discussed later in this article, we feel that any effort to exclude personnel from contact with the drug poses an extremely difficult problem and is of compelling current interest.

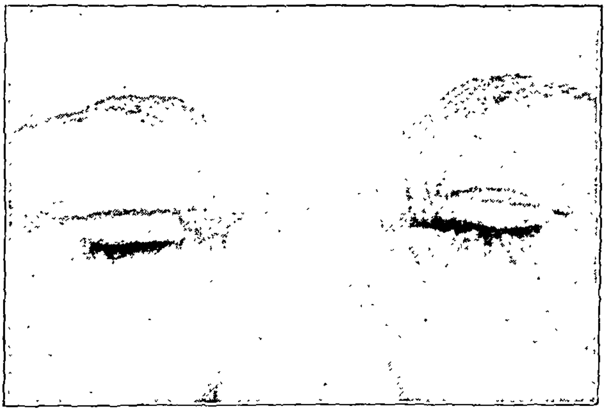

Fig. 2.—Periorbital edema occurring in nurse M. K. G. as part of a generalized reaction following a cutaneous test dose of 100 units of streptomycin.

Sensitivity to streptomycin in all our cases was characterized by an initial erythema followed by pruritus and a papulovesicular eruption. The pruritus constituted a most distressing symptom. In 2 patients there was actual denuding of the skin (fig. 1) over the terminal phalanges of the thumbs and index fingers of both hands. This was considered to be the result of more frequent contact of these areas with the drug in the handling of syringes and needles. Five of the 6 patients showed involvement of the periorbital areas, manifested by a moderate to severe edema of both lids associated with pruritus and photophobia. The conjunctivas were not involved.

Involvement of the periorbital areas was undoubtedly due to autoinoculation. This was exemplified by what many will recognize from personal experience as a not uncommon and somewhat amusing occurrence. One of the nurses while being interviewed unconsciously rubbed her nose and eyes three times, maintaining positively at the same time that she was careful to keep her hands away from her face.

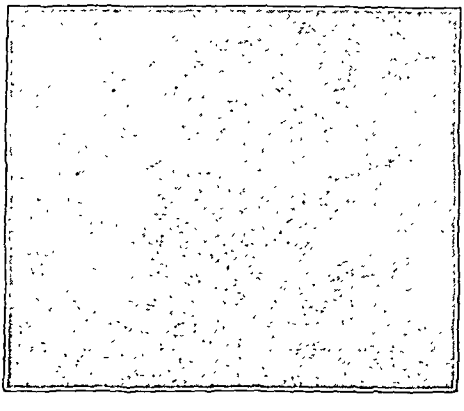

Fig. 3.—Strongly positive cutaneous reaction following intradermal administration of 100 units of streptomycin.

The following case report is representative of the *onset and course in all 6 cases.*

REPORT OF CASE

Nurse M. K. G. had been on a ward where she administered streptomycin daily over a period of eighteen months, when she first noted the characteristic appearance of erythematous areas over the dorsal aspects of several fingers of both hands. This eruption was quickly followed by severe pruritus of the involved areas. Within the next few days she began to show puffiness of her eyes, also accompanied by itching. Because of the recent acquisition of bifocal lenses, this nurse ascribed her eye symptoms to the use of her new glasses. However, from the lesions on her hands, together with a history of contact, and in the light of our recent experience with this entity, we felt that this was a case of streptomycin sensitivity. An intradermal test with 100 units of streptomycin in 0.1 cc. of isotonic solution of sodium chloride was done. This test dose was followed by a severe response. Within twelve hours the periorbital edema noted in figure 2 developed, and the patient experienced a pronounced photophobia. She also had a 4 plus local reaction (fig. 3) measuring 20 by 35 mm., and a flare-up of the lesions on her hands. Her urine was essentially normal but her blood count revealed eosinophilia (19 per cent). She was placed on diphenhydramine hydrochloride ("benadryl"), 50 mg. four times daily for three days, with little or no response. "Pyribenzamine hydrochloride" (tripelennamine hydrochloride) was then administered, 50 mg. four times daily, with definite relief of symptoms within twelve hours. She returned to duty within two weeks after the original onset. This greater efficacy of "pyribenzamine" as compared with "benadryl" medication was uniform in the 3 of our cases in which it was employed for relief of symptoms.

Since these lesions simulated dermatophytoses in some respects, smears and cultures were made from scrapings of the lesions. Smears were negative and cultures showed no growth on blood agar and Sabouraud's mediums after five weeks.

Since these nurses in all instances were in intermittent contact with the administration of streptomycin for periods varying from eight to eighteen months, and manifested sensitivity to the drug only during the past three months, it is probably safe to assume that this type of reaction will develop only after a prolonged period of contact with the drug—i. e., after several months. However, the possibility that sensitivity will develop in the absence of signs and symptoms thereof is thought to be of considerable importance, inasmuch as these persons may be considered potentially subject to an outbreak of dermatitis. Conceivably, this might well occur, with continued exposure tending to augment the sensitivity already present. Furthermore, it is an obvious possibility that many of these persons may some day require the drug and be unable to be benefited because of this acquired sensitivity.

These factors constitute a definite occupational hazard for nurses, pharmacists, laboratory technicians or any one concerned with the administration or handling of the drug. As a consequence, it was considered worth while to do cutaneous tests for the entire nursing staff, the laboratory technicians and pharmacists at this hospital with the intention of instituting a program of desensitization for positive reactors.

The following method was used in the cutaneous tests. A group of 24 persons consisting of physicians and clerical workers was used as a control series. None of these persons had had any actual contact with streptomycin. This group was subdivided into four equal lesser groups and 10, 25, 50 and 100 units of streptomycin per 0.10 cc. of isotonic solution of sodium chloride was administered intradermally to each of these groups, respectively. There were no positive reactors among the controls. One hundred units of streptomycin was administered intradermally to 97 members of the nursing staff. Seven persons (7.2 per cent) gave definitely positive reactions in twenty-four hours. There were doubtful positive reactions in 6 persons (6.2 per cent) in twenty-four hours. Patch tests done on 3 nurses resulted in two positive reactions in twenty-four hours. The patch test done on the third nurse elicited no reaction for three days, during which time she was receiving "pyribenzamine," 50 mg. every four hours, for severe pruritus accompanying her dermatitis. Three days after cessation of "pyribenzamine" medication, this nurse's patch test elicited a strongly positive reaction, indicating a probable inhibition of the cutaneous test by the antihistaminic drug. It is felt that the patch test gives inconstant results because of the difficulty of regulating the concentration. For this reason the intradermal test was adopted. By this method, cutaneous tests will be repeated every four months in an attempt to detect early cases of sensitivity.

As prophylaxis against the development of any further sensitization in like manner, the practice has been established of wearing rubber gloves, with hand washing before and after the handling of streptomycin and of the syringes and needles used in its administration. During the search for possible contaminating practices, it occurred to us that over a period of months "inadvertent nebulization" during sterilization of needles and syringes might well be etiologically significant. Therefore, it is now the practice to allow all sterilizers to cool before opening, in order that there will be no exposure to any emanating steam. A better plan, if feasible, would be to centralize the sterilization of syringes and needles. To date, this plan has not been considered suitable for adoption at this institution.

Protective creams such as those used against flash burns in the armed services might be given a trial, but are not thought to offer the best protection and have not been used at our hospital.

It is strongly urged on the basis of these findings that intradermal testing be performed as outlined in institutions where streptomycin is used at all extensively, and that the prophylactic measures outlined be put to use. With the ever expanding number of antibiotics employed in modern therapy, the reminder that a high index of suspicion be maintained with respect to development of sensitivity to these agents is considered timely.

Allorhythmias.—Two beats following each other within a short time and separated from the next identical group by a longer diastole are classified among the allorhythmias which are called bigeminy or coupled beats. This term, coined prior to the electrocardiographic era, includes, however, at least three different disturbances. First, the succession of groups in which each beat of the basic rhythm is followed by a premature contraction; in this instance, the term bigeminy as a synonym for coupled rhythm is generally accepted. A second form includes examples of an allorhythmia which was later recognized with the aid of the electrocardiograph as due to an auriculoventricular block; a 3.2 block, for instance. The third disturbance is a rare condition which Wenckebach named "true bigeminy." In this type, both beats of each group look alike in the electrocardiogram, for they originate in the same focus.—Scherf, David, M.D. (New York) and Romano, F. J., M.D. (Buenos Aires, Argentina) Extrasystoles in Groups, *American Heart Journal*, page 81, January 1948.

THE HEMORRHAGIC TENDENCY IN CONGESTIVE SPLENOMEGALY (BANTI'S SYNDROME)

Its Mechanism and Management

LEANDRO M. TOCANTINS, M.D.
Philadelphia

This paper is an exposition of some concepts of the mechanism of the hemorrhagic disorder encountered in Banti's syndrome (congestive splenomegaly, portal hypertension), of means for the recognition of its manifestations and of methods found useful in the control or amelioration of the tendency to bleed. The discussion that follows rests on observations made on 22 patients for whom a diagnosis of Banti's syndrome seemed indicated and who had had bleeding in one form or another. In 9 of the patients evidence of cirrhosis was obtained clinically, at operation or at necropsy. From the histories, it was probable that splenomegaly had preceded the manifestations of cirrhosis. Hematemesis or melena was the form of bleeding in 17 patients. Epistaxis, hematuria, vaginal bleeding, purpura and hemothorax were some of the other forms. The incidence of hemorrhagic complications in patients with this syndrome is difficult to estimate. Except for a brief mention of epistaxis, Banti said little about bleeding in his original article.[1] He seemed to attribute the anemia to the effect of endogenous toxic substances elaborated by the spleen. In Barg and Dulin's [2] series of 43 patients, 39 per cent had hematemesis and 25 per cent epistaxis. Of the patients reported by Rousselot [3] to have died after splenectomy, 8 (38 per cent) had had hemorrhage. Bleeding (epistaxis, melena, purpura) of a slight character, giving rise to no systemic symptoms, is probably common in patients with this syndrome, but it is often overlooked. In many patients this symptom overshadows all others and forces consideration of measures for its control.

Clinical Recognition.—The syndrome has clinical features common to several diseases. Congestive splenomegaly must be differentiated from the various types of splenomegaly, with or without anemia, leukopenia and thrombopenia, and a number of conditions giving rise to gastrointestinal hemorrhage. When the syndrome is fully developed or when it has followed portal cirrhosis, there is usually little difficulty in recognizing it. In the early phase, it is nearly always confused with other hemorrhage-producing lesions of the gastrointestinal tract. Pain and digestive disturbances are seldom complaints. A sense of heaviness in the upper part of the abdomen after eating may be the only complaint at first. An examination of the abdomen immediately after a severe hemorrhage, and for a week or so afterward, may not disclose enlargement of the spleen.

Case 1.—A white girl 15 years of age was admitted to Jefferson Medical College Hospital on Oct. 16, 1942, because of a sudden hematemesis. Her hemoglobin content was 4.8 Gm. per hundred cubic centimeters, with 1,090,000 red blood cells, 9,200 leukocytes and a platelet count of 80,000. A special search was made for any mass or enlarged organ in the abdomen. The spleen was not palpable. The patient was given four transfusions, and on October 26 (ten days after the onset of vomiting of blood) the spleen was felt for the first time. At operation, eight days later, the spleen weighed 610 Gm. and was turgid with blood; histologic examination of sections revealed little increase in fibrous tissue.

Case 2.—A white man aged 23 was admitted to Jefferson Medical College Hospital because of faintness, weakness and the passage of tarry stools. His first attack of hematemesis had taken place seven months before, at which time he had required several transfusions. In the interim he had been in good health. Except for pallor, physical examination at the time of admission to the hospital revealed no abnormality. There were normochromic anemia, leukopenia and moderate thrombopenia. Tests of hepatic function and roentgenographic studies of the gastrointestinal tract gave normal results. Ten days after his admission to the hospital the spleen was first clearly felt on deep inspiration.

The fact that during the early stages of the disease the spleen has not yet become fibrotic is probably what allows it to contract after a hemorrhage. Much of the blood lost through the broken varicosities comes from the spleen; this fact also accounts for the reduced volume of the organ after hemorrhage. Once the vascular defect has been repaired and the tension in the portal circuit is again increased, the spleen once more becomes distended with blood. The succession of these changes, namely, the gradual increase in portal hypertension and the sudden decompression by hemorrhage, followed by a repeated rise in portal tension, accounts perhaps for the periodicity of the attacks of gastrointestinal bleeding in patients with this disease. Spread of the varicosities or loss of distensibility of the spleen because of advanced fibrotic changes may be among the factors in the increase in frequency of the attacks as the patient becomes older.

Case 3.—A man aged 35 had his first attack of hematemesis in 1934. He was treated for gastric ulcer and was free from hemorrhage until July 1939, when he vomited blood for about a week. In February 1940, August 1941, August 1942, April 1943 and September 1943, he had similar attacks, each of which required hospitalization and several transfusions. Between these attacks he was in perfect health. About a month before the last attack he was thoroughly examined, and the spleen was then felt about 6 cm. below the costal margin. On the day after the onset of the last hematemesis the erythrocyte count was 1,600,000 per cubic millimeter, and the spleen could not be felt on deep inspiration. One month later it was palpated 4 cm. below the costal margin; it weighed 357 Gm. when removed.

A few other differentiating points are helpful. Persistent leukopenia and thrombopenia, with little or no alteration after a hemorrhage, are characteristic signs. Absence of roentgenographic evidence of gastric or duodenal ulcer and enlargement of the splenic shadow are suggestive. A history of severe trauma to the abdomen two to three years before the first attack of hematemesis is occasionally obtained. (Such a history was given by 2 patients in my series.)

Examination of the sternal marrow may help to eliminate the anemias, leukopenias and thrombopenias due either to hypoplasia of the bone marrow or to leukemic infiltration. In the earliest stages of the syn-

drome, the bone marrow is hyperplastic, especially the erythropoietic series. If there is thrombopenia, it may be difficult to differentiate the syndrome from "idiopathic" thrombopenic purpura. In the later stages, when there are ascites and severe impairment of hepatic function, the bone marrow may be hypoplastic.

Roentgenologic examination is helpful in the demonstration of varices in the esophagus, which are usually located in its lower portion.[4] Lateral and right oblique views are best obtained at various stages in the progress of the barium sulfate mixture, with the patient in a horizontal position, or even in the Trendelenburg position, to favor a slow emptying of the esophagus and to accentuate the varicosities. The varices, when not fully developed, will at first appear only as large folds of the mucosa, about the thickness of a pencil, differing from the usual esophageal folds in their tortuosity. If the examination is made only a week or so after a hemorrhage, the veins will probably not stand out, since the hypertension in the portal circuit has been temporarily reduced. In the far advanced case, rounded, ampulla-like, irregularly spaced folds of the mucous membrane may be observed ("pearl necklace" formations, fig. 4).

Endoscopic examination, attended with small risk in the hands of an experienced worker, helps to identify the varicosities and to determine their approximate size. The examination preferably should be conducted a few months after the bleeding has stopped, when there is a greater chance of detecting distended veins.

MECHANISM

Cause of Excessive Bleeding.—The hemorrhagic tendency of this syndrome is due both to local and to systemic causes. All portions of the hemostatic mechanism (vascular, extravascular and intravascular)[6] are usually involved.

1. Vascular defects. The involved vessels are the branches of the portal system, usually those in the esophagus or the rectum (fig. 1). The wall of the vein is stretched, undermined and ruptured. Cicatricial rings distort the lumen of the vessel and lead to dilatations.

2. Extravascular defects. The mucosa overlying the distended veins is thinned and eventually sloughs, leaving a "varicose ulcer," which contributes to the erosion of the wall of the underlying vein.[6] These defects are difficult to visualize, gastroscopically or roentgenographically during life. Even at autopsy the veins must be injected in order to disclose the defective areas.[6] As in the case of punctured tire tubes, inflation is necessary to locate the site of the leak.

3. Intravascular defects. The thrombopenia and hypoprothrombinemia of this syndrome hinder the prompt formation of an effective hemostatic plug at points where small ruptures of the veins have occurred. This delay allows the vascular defect to remain unrepaired, and the flow of blood is unchecked until large amounts have been lost. The thrombopenia may result from overactivity of the spleen, both in its effect of hematopoietic depression and through increased destruction of platelets in the enlarged, overdistended organ, which holds large amounts of slow-moving or stagnant blood. The fact that thrombocytosis, with subsequent stabilization of the platelet count near normal levels, follows splenectomy is an indication that the spleen contributes directly to the thrombopenia. The hypoprothrombinemia probably results from transient or permanent impairment of hepatic function. In the early stages of the syndrome, the administration of a vitamin K preparation (1 to 2 mg. of menadione sodium bisulfite U.S.P. daily, parenterally) promptly restores the prothrombin level to normal. A slow or no response is a fairly dependable indication of an advanced degree of hepatic insufficiency; delay in or absence of response is usually encountered in the later stages of portal cirrhosis.

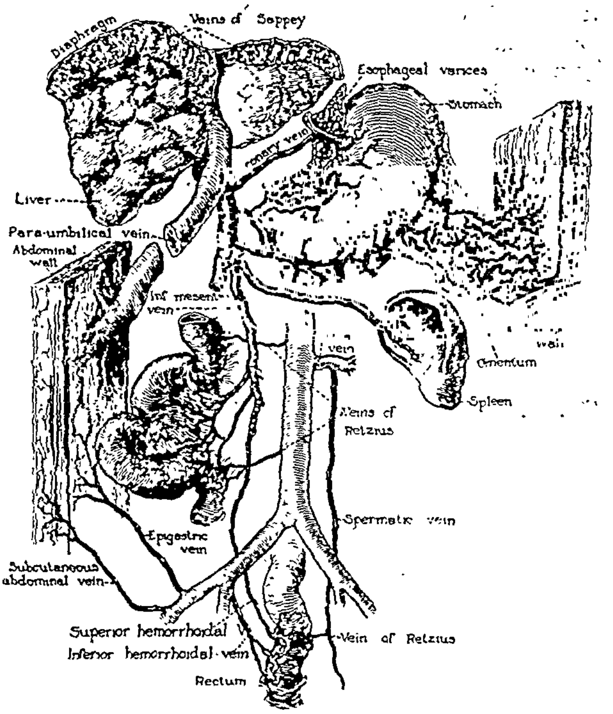

Fig. 1.—The common venous anastomotic channels between the portal circulation and the systemic venous circulation (from McIndoe[6]).

Added to this complex defect in hemostasis is the increased stress placed on the portal vessels by the hypertension within them. It is this hypertension that causes the dilatation of the portal and collateral vessels and leads to distention of the spleen. Congestive splenomegaly and the accompanying changes of Banti's syndrome are now considered to develop as a result of any pathologic process (inflammatory, neoplastic, parasitic or fibrotic) which interferes with the flow of portal blood through the liver or at any point in the splenic or portal vein.[7] In the majority of cases, the obstruction is only partial and has developed gradually. Thrombophlebitis of the splenic or portal veins, portal cirrhosis and cirrhosis due to schistosomiasis are the commonest causes of obstruction. Obstruction in the mesenteric veins leads to formation of varicosities and to intestinal bleeding; but unless the portal or splenic veins become involved by extension, it will not produce the syndrome.[3] Except in frank cases of portal cirrhosis, the exact type and location of the obstruction is difficult to determine clinically, and sometimes pathologically. Roentgenographic visualization with injections of radiopaque substances at the time of the operation has been tried.[7] In figure 2 are outlined the changes which follow obstruction in various portions of the portal circulation.

The patient with this syndrome has, then, a multiple defect in hemostatic function (phlebectasia, thinning or ulceration of the overlying esophageal mucosa, thrombopenia and hypoprothrombinemia) and an exaggerated stress on the vessels due to the hypertension within them. The increase in the total blood volume, due principally to an increase in the plasma volume, which is often seen in patients with cirrhosis, may help to augment internal stresses on the vessels. It is the combination of these exaggerated stresses, poorly offset by a defective hemostatic mechanism, that renders the hemorrhages massive and difficult to control.

MANAGEMENT

During the phase of acute bleeding, efforts must, of course, be made to replace the blood lost and to reduce or arrest the bleeding. The reduction in the portal hypertension which follows a hemorrhage may in itself bring about arrest of the bleeding if the patient remains quiet and the speed of replacement and the amount of blood and fluid used are judiciously managed. As with most hemorrhagic disorders, it is well to be content with giving only enough blood to maintain the patient's circulation, without attempting to raise the hemoglobin concentration to normal levels with excessive transfusion. If the patient's hemoglobin level is 7 Gm. per hundred cubic centimeters or thereabouts, and his blood pressure, pulse and circulation are in general well maintained, it is better to let well enough alone. The general condition of the patient, particularly the state of his circulation, is a better indication of the amount of blood to be given and the time of administration than the hemoglobin concentration or the erythrocyte level. Administration of menadione sodium bisulfite U.S.P. 4 mg. daily, hypodermically, should be maintained during the hemorrhagic phase. Arrest of the hemorrhage with local measures is difficult because the bleeding vessels are not easily accessible. If the bleeding continues in spite of these conservative measures, a trial of local compression may be made. A small intestine tube provided with a distensible bag is introduced into the stomach. The bag is inflated, pulled up against the cardia, fixed and held in place for several hours (fig. 3). Liquid food may be instilled through the tube itself, and gastric contents may be aspirated to ascertain when bleeding has stopped.

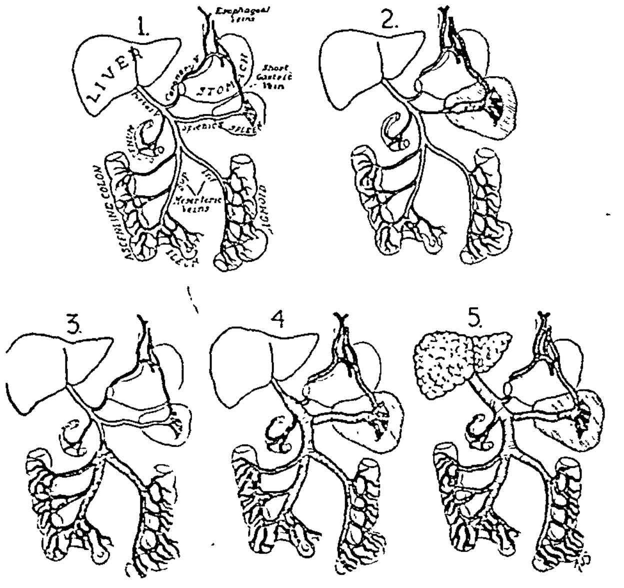

Fig. 2.—Schematic representation of the effects of extrahepatic and intrahepatic obstruction of the portal vein on some of its tributaries. Anatomic variations of the aforementioned pattern (encountered not uncommonly) will, of course, alter the scheme. *1* shows the portal circulation; *2*, obstruction of the splenic vein, splenomegaly and dilatation of the esophageal veins; *3*, obstruction of the mesenteric vein (bleeding with this type of obstruction is chiefly from the small and the large intestine); *4*, obstruction of the portal vein itself, outside the liver, and *5*, intrahepatic portal obstruction due to cirrhosis. The last type calls for the most extensive collateral venous anastomosis, such as is shown in figure 1.

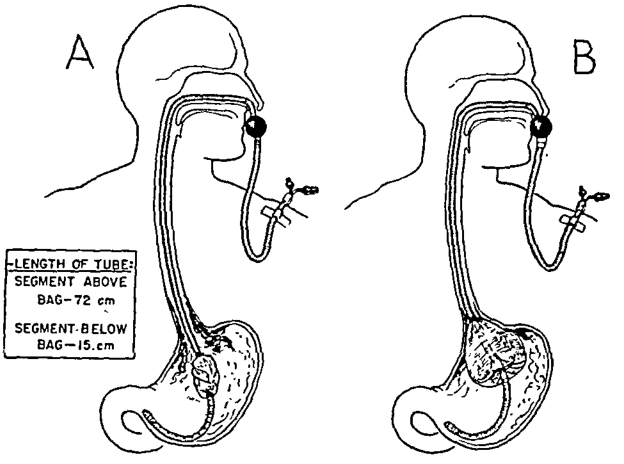

Fig. 3.—Tamponade of the cardiac end of the esophagus, with use of a specially designed tube (assembled by George P. Pilling & Son Co., Philadelphia). This procedure was originally practiced with a Miller-Abbott tube in 1944 by Dr. Edward W. Bixby (also, Rowntree, L. G., and others, Intraesophageal Venous Tamponage: Its Use in a Case of Varical Hemorrhage from the Esophagus, J. A. M. A. **135:** 630 (Nov. 8) 1947). (*A*) The tube with the deflated bag is passed into the stomach. (*B*) The bag is inflated (with 50 to 75 cc. of air) and maintained so. The tube is then drawn up until the bag is pressing against the cardiac end of the stomach. The perforated ball is slipped up against the nostril, and a loop of adhesive tape is passed around the tube just outside the ball, to prevent its slipping down. Aspiration of the gastric contents, after preliminary washing out of the stomach, will indicate whether or not bleeding is still going on. At four to six hour intervals, the bag should be deflated and allowed to remain so for twenty to thirty minutes. This procedure reduces the possibility of development of necrosis of the compressed mucosa. After a period of decompression, aspiration may be tried, to see whether there has been any bleeding. During compression, the patient may be fed through the distal segment of the tube.

Case 4.—A white man aged 53 was admitted to the Pennsylvania Hospital in May 1945, because of severe hematemesis and melena. He was known to have cirrhosis and esophageal varices. In spite of several transfusions of blood, his erythrocyte count remained under 1,000,000, and he continued to vomit large amounts of blood. Dr. Edward W. Bixby Jr., medical resident in Dr. Garfield Duncan's service, suggested using direct compression on the presumptive bleeding area. He placed a Miller-Abbott tube in the patient's stomach, inflated the bag to a pressure of 20 mm. of mercury and pulled it up against the cardia. The tube was fixed in place, and the position of the bag was checked fluoroscopically. The tube was left undisturbed for about thirty-six hours, during which there was no evidence of bleeding. Meanwhile, it was possible to raise the patient's red cell count to 4,200,000 with subsequent transfusions, without further loss of blood. He left the hospital three weeks later, in good condition.

As soon as the acute phase of bleeding is over, consideration must be given to measures for its permanent control. These measures are directed toward reduction of the portal hypertension and correction of the phlebectasia, thrombopenia and hypoprothrombinemia. The success of any, or all, of these measures depends chiefly on the character and site of the block in the portal circulation, the degree of functional impairment of associated organs, such as the liver, and the patient's general condition. Patients may be separated into two large groups: 1. Patients under 40, with hematemesis, anemia, leukopenia and thrombopenia; slight or no splenic enlargement during the hemorrhagic period, and moderate enlargement between attacks. The bone marrow is hyperplastic, especially the erythropoietic series, and hepatic function is well preserved. 2. Patients over 40, with hematemesis, melena, anemia, leukopenia and thrombopenia; normal or hypoplastic bone marrow; slight hyperbilirubinemia; occasional or permanent ascites; large, noncontractile spleen, and moderate or severe impairment of hepatic function, as indicated by poor elimination of sulfobromophthalein sodium U.S.P. and little or no increase in prothrombin after parenteral injection of a vitamin K preparation.

In patients of the first group there may be an extrahepatic or an intrahepatic block with well preserved hepatic function. The condition in this group is, of course, often responsive to therapeutic measures. In the second group there is almost certainly an intrahepatic block, as well as advanced hepatic derangement; little or no response to treatment may be expected in this group. Between these two groups is a large number of patients with combinations of defects of variable severity. It is by balancing the extent of the disability and the threat to the patient's life from the attacks of bleeding against the degree of impairment of organs such as the liver, bone marrow and the circulatory apparatus that a decision is reached as to the best procedure to follow.

Correction of the portal hypertension is attempted with splenectomy and/or diversion of the portal blood into the systemic circulation by one of several methods (omentopexy or portacaval or splenorenal shunts).

Splenectomy.—The decision for removal of the spleen in patients with Banti's syndrome rests principally on the following reasons:

(1) About 40 per cent of the blood flowing through the portal vein comes from the spleen, to which it is brought, of course, by the splenic artery. Splenectomy will then help reduce the congestion in the portal circuit by diminishing the amount of blood flowing through the liver. Some benefit might be expected, therefore, to occur even in patients in whom block of the portal circuit is intrahepatic and whose hepatic function is preserved to some extent.

2. When the obstruction is in the splenic vein itself, splenectomy is obviously curative, since it carries with it the elimination of the obstructive factor.[7]

3. In most patients, the removal of the spleen is followed by intensified hematopoiesis, with return of the platelet count to normal. One of the defects in the hemostatic mechanism contributing to the hemorrhage is thereby corrected.

It is not as yet possible to select with full confidence the patients who will be benefited by splenectomy. In those patients with the early stages of the disease or in those with a more advanced stage, yet without severe impairment of hepatic function, the results are often good. Hemorrhages from the alimentary tract may disappear entirely; often they are only diminished in frequency and intensity, while occasionally they may be aggravated. The over-all operative mortality is about 25 per cent.[2] About 50 per cent of the operative deaths are due to hemorrhage from the operative site; patients with long-standing Banti's syndrome often have adhesions of the spleen to the abdominal wall which make removal of the spleen difficult and separation of which leaves large raw areas exposed. Mesenteric or portal thrombosis and pulmonary embolism account for most of the remaining postoperative deaths. These complications occur in five to twenty days after the operation, and they can probably be prevented with heparinization. Occasionally ascites is relieved by splenectomy.[2] The duration of life seems to be appreciably prolonged by the operation,[2] principally, perhaps, because of the discontinuance or diminution in severity of the hemorrhages.

In my series of 22 patients, splenectomy was performed in 9. There were 2 deaths, 1 fifteen and the other twenty-one days after operation, both of thromboembolism. The remainder of the patients have, with 1 exception (a patient who died four years after operation), survived seventeen, sixteen, seven, seven, five and four years, respectively. Two of these patients (the ones who survived seventeen and sixteen years) have been free from attacks of hematemesis since the operation. The rest of the patients have had at least one attack of bleeding; in most instances the attacks have not been so severe as before the operation.

It is obviously impossible in many instances to tell the exact site of the obstruction without surgical intervention. Once the abdomen is open, the surgeon must, among other things, investigate the condition of the liver and of the portal bed at the hilus of liver and determine the presence of any collateral circulation and the state of the area about the spleen. If the dilated veins are situated principally in the left half of the abdominal cavity and there is little or no dilatation in the cecal region, it is probable that the splenic vein alone is involved. If, in addition to splenomegaly, the mesenteric veins about the ascending and descending colon are distended, it is almost certain that the portal vein, extrahepatically or intrahepatically, is obstructed; under these conditions, any benefit derived from splenectomy may be traced to the reduction in the volume of blood passing through the portal circuit and the subsequent thrombocytosis. Obstructive factors cannot always be demonstrated, even when effective methods are employed. In as many as 30 per cent of the patients in one series[3] no such factors could be demonstrated.

The difficulties that sometimes attend splenectomy in these patients make it desirable, whenever it is possible and indicated, to perform the operation before the stage of widespread infarction and adhesions of the spleen to the parietal peritoneum, omentum and other organs. If adhesions are extensive, it may be preferable to ligate the splenic artery or to clamp the pedicle before attempting to free the spleen from its attachments, because of the abundant bleeding from the surface of adhesions. The raw surfaces should be peritonealized or covered with strips or films of hemostatic absorbable gauze ("gelfoam") and an oxidized cellulose. Autopsy has sometimes disclosed hemorrhage in and about the splenic bed, even though the pedicles were well tied.[8] The blood probably came from the raw, granulating adhesions, which, perhaps, bled little during the operation itself.

Extension or development of thrombosis in other sections of the portal system would seem a more likely complication of splenectomy for this syndrome than for other disorders. The already existing involvement of the veins in the portal circuit, together with the changes in the blood after operation, probably accounts for the high incidence of thrombosis (particularly mesenteric) after splenectomy for Banti's syndrome. Heparinization and early active mobilization should aid in preventing complications. These measures are especially indicated with those patients who have had a striking rise in the platelet count a day or two after the operation (fig. 4).

Hematemesis or melena appearing in the second week after the operation is a bad omen. It nearly always means that the obstruction has not been relieved and that there has been extension of the thrombotic process into most of the branches of the portal vein previously unobstructed.

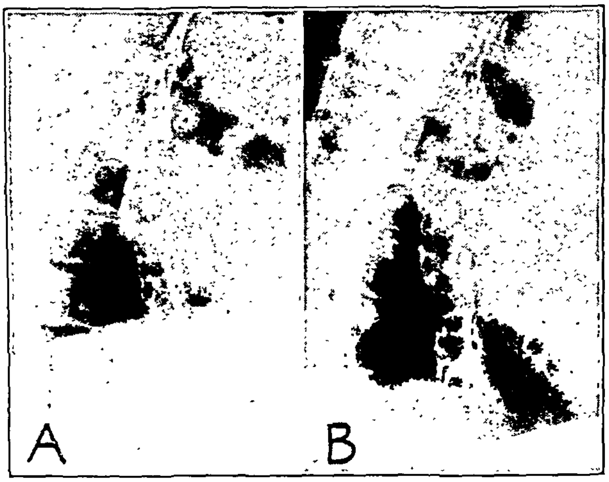

Fig. 4.—*A*, preoperative esophagogram of O. C., a white man 33 years of age, who had four severe attacks of hematemesis in two years, epistaxis and purpura, with platelet counts under 40,000 per cubic millimeter. There was no clinical or operative evidence of cirrhosis. Heparinization was continued for ten days after splenectomy. The patient was living four years after the procedure, with only one attack of hematemesis. He had required no transfusion since the splenectomy. *B*, appearance of esophagogram four years after splenectomy. The platelet count was 320,000 per cubic millimeter; results of other studies of hemostatic function were normal.

Other measures have been tried, usually in association with splenectomy, to relieve the portal hypertension. Omentopexy, either by placing the omentum in contact with an abrased surface of the liver or by suturing the omentum against the split rectus muscle, has not produced uniformly beneficial results.[7] The latest attempts at diversion of the portal flow into the systemic circulation have consisted in anastomosing the portal vein with the vena cava, end to side, using the nonsuture technic with "vitallium" (a cobalt, chromium, molybdenum alloy) tubes.[9] Another variant, anastomosis of the splenic vein with the stump of the left renal vein (after splenectomy and removal of the left kidney) does not seem so effective[9] and involves greater trauma and, probably, a higher risk. The technic of anastomosis of these vessels is exacting and requires a high grade of skill. Results so far reported[10] are encouraging enough to warrant the continued trial of these surgical procedures in critically selected patients.

Correction of the Vascular Defect.—The varicosities themselves are best managed by injecting into them a sclerosing solution through the esophagoscope.[11] It would seem, however, that this procedure should be used in patients who have had splenectomy and who continue to have attacks of hematemesis. Like ligation of the coronorary vein, sclerosis of the natural anastomotic paths,[12] without simultaneous diminution of the blood draining into them, will tend to increase the tension in an already overburdened portal circuit. Some of the patients in my series have been treated with this method by Dr. Louis H. Clerf,[13] who expressed the belief that the method has some value. "In a number of patients whom I have treated over a period of several years there is unquestioned evidence that either the bleeding has been entirely inhibited or the hemorrhages have been minimal. Patients who previously had two or three disabling hemorrhages annually have gone for long periods without even slight bleeding. It is, of course, necessary to reexamine patients several times annually, for the vessels do recanalize and additional injections are required."

Correction of the Defects in the Blood.—One of the defects, thrombopenia, is often corrected by splenectomy. Patients whose platelet count is normal before splenectomy but who have had severe attacks of hematemesis cannot expect much amelioration of the bleeding after the operation; the hemostatic defect was perhaps principally vascular in origin and was apparently inadequately compensated, even when the coagulability and the platelet content of the blood were normal.

The hypoprothrombinemia can be overcome in those patients whose hepatic function is not too far deranged by means of the use of vitamin K preparations and a dietetic regimen designed to enhance hepatic function. These measures, of course, should be a part of the preparation for any of the operative procedures mentioned previously.

SUMMARY

Defects in nearly all portions of the hemostatic mechanism are responsible for the tendency to bleeding in patients with Banti's syndrome.

The defects are thinning and dilatation of the veins serving as tributaries of the portal vein and anastomotic collaterals, ulceration of the gastroesophageal mucosa overlying the veins, thrombopenia and hypoprothrombinemia. Hypertension in the portal circulation increases the already existing stresses on the defective vessels.

Transfusion, administration of a vitamin K preparation and, possibly, tamponade with inflatable bags are measures for the arrest of bleeding from esophageal varices during the acute phase.

Splenectomy, injection of sclerosing solutions into the distended vessels, diversion of the portal blood flow into the systemic circulation by anastomotic operations, and measures designed to support hepatic function have been used to control or to diminish the attacks of hemorrhage.

1025 Walnut Street.

ABSTRACT OF DISCUSSION

Dr. William Dameshek, Boston: Conditions characterized by splenomegaly, and associated with anemia, leukopenia, granulocytopenia, thrombopenia or pancytopenia, may be due to numerous causes, including congestive splenomegaly. For instance, chronic infectious splenomegaly due to tuberculosis, typhoid and malaria, or to Gaucher's disease and a host of other conditions, are associated with various types of cytopenias. It has been the custom indiscriminately to call all these conditions Banti's syndrome. Much is lost in so doing from the standpoint of exact diagnosis. To be sure, if the patient has hematemesis, there is the likelihood that esophageal blood vessels are grossly enlarged and that the splenomegaly is "congestive" in type. There is a syndrome in children which was first fully described by Richard Smith and his co-workers at the Children's Hospital in Boston, in which thrombosis of the splenic vein occurs in association with hemorrhage, not from esophageal varices, but from the vasa brevia of the stomach. After hemorrhage in children who have this condition, the spleen may not be palpable, as Dr. Tocantins pointed out; but, instead of the common posthemorrhagic leukocytosis, there is leukopenia. Thus, in the presence of hematemesis with leukopenia, one should think of the possibility either of this particular syndrome or of the broader syndrome of congestive splenomegaly. Dr. Tocantins has analyzed the hemorrhagic tendency in this disorder. Ordinarily, one thinks simply of the great distention of the collateral blood vessels as the cause of the bleeding, but he has pointed out that the platelets are usually definitely reduced. I believe this reduction of platelets is due to a hypersplenic effect. The spleen, when enlarged, seems to have an effect on the marrow, reducing the production of the platelets from the megakaryocytes. A variety in choice of treatments of congestive splenomegaly with hematemesis is available; for example, one may use no treatment except, perhaps, transfusion, merely tiding the patient over this one particular hematemesis. Curiously, some patients remain free from episodes of bleeding for many years without further treatment. Or one may choose splenectomy. I think splenectomy should be chosen in cases in which pronounced hypersplenic effects, i. e., extreme thrombopenia or leukopenia, are observed. In such cases, removal of the spleen often relieves the hematologic abnormality. In severe cases with recurrent hematemeses, one should seriously consider one of the shunt operations, of which there are two: the splenorenal shunt, as developed by Blakemore and his collaborators, and the portal vein–vena cava anastomosis. This operation is newer and perhaps more difficult technically; but it offers a better possibility of diminishing the great degree of portal hypertension.

Dr. Cecil O. Patterson, Dallas, Texas: We are indebted to Dr. Tocantins for his presentation of a most timely subject. It should be emphasized that in cases of Banti's syndrome, although hemorrhage is periodic, one cannot anticipate which recurrence will be fatal. Of 24 patients whom my colleagues and I treated for hematemesis from esophageal varices, only 1 proved to have gastric varices. In 9 patients varices were confined to the lower third of the esophagus, and in 9, to the lower half; in 8, varices extended throughout the esophagus. Thus, I feel that further emphasis should be placed on the sclerosing therapy of these varices with injections through the esophagoscope. I have, during the past three and one-half years, given sodium morrhuate injection U. S. P. (5 per cent) to 24 patients, 3 to 66 years of age, whose chief presenting complaint was that of massive hematemesis, which proved to be from esophageal varices. Caution is, of course, necessary; for example, anaphylactic reactions to the injectable sclerosing agent have been reported. The esophagus lies directly against the pericardium, the aorta and other vital structures, to which trauma must be avoided. Such hazards are remarkably rare as compared with the known high incidence of fatal hemorrhage when the varices are untreated. Three patients with cirrhosis of the liver were relieved of ascites, with restoration of blood and protein reserves, after injection of sclerosing fluids. No apparent complications, such as hemorrhage or aggravation of ascites, have appeared subsequent to the injections per se. Preferably, after splenectomy, or if necessary before, injection of the varices should also be done, if hematemesis is to be prevented. Four of our patients (ages 6, 19, 13 and 34) had had eighty-one massive hemorrhages after splenectomy, whereas, now three and one-half, three, one, and one year, respectively, since the beginning of sclerosing therapy, an anticipated incidence of hemorrhage of twenty-seven was reduced to two, neither of which was fatal. Dr. Herman J. Moersch (*Proc. Staff Meet., Mayo Clinic* **21**:410 [Oct. 30] 1946) reported on 12 patients, with no recurrence of hemorrhage three to seven years after completion of sclerosing treatment of the esophageal varices. To my knowledge, no other method has been proposed which can so effectively protect these patients from recurrence of hematemesis. In mentioning sclerosing therapy of the esophageal varix, there is no intention of minimizing the over-all care of patients with Banti's syndrome, so capably discussed by Dr. Tocantins.

Dr. C. J. Watson, Minneapolis: Dr. Tocantins, how frequently in your series was actual ulceration of the esophageal varices encountered? Do you think this ulceration is related to peptic digestion with the gastric juice? In my experience, ulceration has been encountered infrequently. Often, in fact, it is difficult to find the point from which the bleeding occurs, and if one does find it, the lesion consists only of a small linear slit, a true ulcer being unusual.

Dr. Leandro M. Tocantins, Philadelphia: With reference to Dr. Dameshek's objection to use of the term "Banti's syndrome," I agree with him in part, but it seems to me, after consideration of all the factors, that the term still has its uses as a purely clinical designation. The diagnosis of Banti's syndrome, as it was stressed during the presentation, is mostly one of exclusion of conditions that resemble it but have a different pathogenesis. A number of entities, as Dr. Dameshek said, include many of the clinical features of this syndrome, but when these conditions are accompanied with overwhelming hemorrhages from the gastrointestinal tract, and particularly with the vascular changes that were mentioned, a clinical diagnosis of Banti's syndrome may be made, provided other things, such as leukemias and the various types of anemia and causes of splenomegaly, are excluded. Dr. Patterson's figures are impressive, and I am assured by Dr. Louis Clerf, the bronchoscopist at Jefferson Medical College Hospital, that he is favorably impressed too, with the use of sclerosing injections for esophageal varices. I should like to emphasize that these injections should follow or accompany splenectomy and should not be undertaken before it, since the vascular sclerosis deprives the patient of some of the natural anastomotic channels he has built up. As to the presence of ulcerations over the varicosities themselves, I recall in my own experience 1 such case, encountered at autopsy. The ulcerations were, of course, detectable, because it is possible at autopsy to visualize the entire stomach and to make a careful search for them, whereas such a search is obviously impossible during life. Dr. McIndoe refers to these ulcerations as a not uncommon occurrence in this disorder. That is all I know of the actual frequency of this complication. Occasionally, one hears of the demonstration of gastric ulcers with roentgenographic methods in patients whose condition is later diagnosed as this syndrome.

Clinical Notes, Suggestions and New Instruments

MEDIASTINOTOMY IN SPONTANEOUS MEDIASTINAL EMPHYSEMA

JAMES R. KARNS, M.D.
and
EDWIN O. DAUE Jr., M.D.
Baltimore

Mediastinal emphysema has been recognized as a clinical entity for over one hundred years, but it was not until 1937 that Hamman[1] called attention to the spontaneous occurrence of this condition and the criteria necessary for its diagnosis. Since Hamman's lucid descriptions[2] there have been reports of numerous cases. The majority of these have been self limited and of short duration. On rare occasions the accumulation of air in the mediastinum has been great enough to produce severe and sometimes fatal impairment of the circulatory system. When this occurs, immediate surgical intervention becomes necessary. The purpose of this report is to present a case of acute spontaneous mediastinal emphysema which required mediastinotomy.

PATHOGENESIS

In 1930, Joannides and Tsoulsos,[3] while working with the problem of air embolism, noted the occurrence of mediastinal and interstitial emphysema and correctly speculated that anything producing increased intrapulmonic pressure could cause mediastinal emphysema. Macklin[4] clearly outlined and proved the accepted pathogenesis. The process begins with rupture of an alveolus within the lung and is furthered by air dissecting along perivascular sheaths to the hilus and into the mediastinum. The etiologic factor may be positive pressure anesthesia, the second stage of labor, influenza, bronchopneumonia, bronchial asthma, atelectasis, straining at stool, heavy lifting, trauma to the chest wall, penetrating wounds of the trachea or bronchus, tracheotomy, artificial pneumothorax or foreign bodies in the tracheobronchial tree.[5]

CLINICAL PICTURE

The symptoms of the condition are one or more of the following: Pain in the chest, vague discomfort or sensation of constriction, dyspnea and cyanosis. The pain may be substernal or precordial and may radiate to the back, shoulder or arm, often simulating the pain of angina pectoris. In lesser degrees a vague substernal discomfort or feeling of constriction may occur. It may be aggravated by respiration, motion or changes in position. Dyspnea and cyanosis are usually not pronounced unless the amount of air in the mediastinum is great or unless there is an associated pneumothorax.

The most characteristic feature in physical examination is the finding of a peculiar sound heard over the precordium described as "crackling, bubbling or churning." This sound is synchronous with the heart beat and is known as Hamman's sign. Other important but less diagnostic signs are: obliteration of cardiac dulness, engorged veins of the neck, face and chest, pneumothorax and roentgenographic evidence of air in the mediastinum. Roentgenographically mediastinal emphysema may be demonstrated in the anterior mediastinum, around the pericardium in the middle mediastinum or along the larger bronchi in the posterior mediastinum. A frequent and helpful finding is an associated pneumothorax.

The emphysema may extend to the neck, trunk, arms, face and at times even the lower extremities. Usually the temperature and pulse rate are not elevated. Electrocardiograms, white blood cell counts and sedimentation rates remain normal.

Awareness of this condition and knowledge of the diagnostic criteria as set forth by Hamman will assure the differentiation of this disease from acute pericarditis, angina pectoris, myocardial infarction, pleurisy, spontaneous pneumothorax and the various causes of cardiorespiratory distress in infants. The necessity of accurate differentiation is self evident as one considers the gravity of the latter diseases.

PROGNOSIS AND TREATMENT

The prognosis in uncomplicated spontaneous mediastinal emphysema is good and requires no more than symptomatic treatment for a short period. Only if the pressure in the mediastinum becomes great, do serious complications result. This more often develops in infants and may lead to sudden death.

Increasing dyspnea, cyanosis and venous congestion are signs of cardiorespiratory distress resulting from progressive mediastinal pressure. When this appears, immediate operation is imperative. The first recorded mediastinotomy was performed by Tiegel[6] in 1911. He supplemented his vertical suprasternal incision by aspiration with bell jar suction. Since that time various methods have been used to provide egress for air trapped in the mediastinum. Incisions have been made in the following regions: the first two intercostal spaces, supraclavicular fossae, in the suprasternal notch[7] and below the xiphoid process. In children, needle aspiration has been used instead of opening the thorax.

REPORT OF A CASE

N. C., a white man aged 57, was admitted to the University Hospital complaining of swelling of the neck and face and difficult breathing.

His past history revealed asthmatic attacks for twelve years and an illness, suspected of being tuberculosis, two years before admission. At this time he had fever and loss of weight but repeated roentgenograms of the chest showed nothing indicative of tuberculosis.

Seventeen hours before admission the patient was awakened in the early morning by a severe coughing attack during which he had a sudden, severe, sharp pain in the upper anterior portion of the left side of the chest and dyspnea. The dyspnea was not severe and seemed to be caused by restriction of breathing due to pleuritic pain. Eleven or twelve hours after onset, his neck and face began to swell and breathing become more difficult.

Physical examination on admission revealed a normally developed white man sitting upright in bed in considerable respiratory distress. His face, up to the zygomatic arch, neck, left forearm, both arms, thighs, scrotum, chest and abdomen were ballooned up by subcutaneous emphysema. His skin and mucous membranes were moderately cyanotic. Veins of the neck, face and upper part of the chest were distended but not pulsating. Crepitus was present to the level of the zygomatic arches anteriorly and to the occipital protuberance posteriorly. The conjunctivas and lower lids were slightly puffy. The trachea was deviated to the right. A greater amount of subcutaneous emphysema was seen over the left side of the chest than the right and respiratory excursions of the left side of the chest were limited. The percussion note was hyper-resonant throughout. Breath sounds were distant. Voice sounds were dimin-

ished over the posterior surface of the left side of the chest. Few scattered rhonchi were heard over the right lung. The cardiac impulse was faintly palpable along the right border of the sternum in the fourth interspace. The heart could not be outlined by percussion. Heart sounds were rhythmic and distant. Crackling sounds were heard over the precordium during cardiac systole and diastole. The blood pressure was 120 mm. of mercury systolic and 80 mm. diastolic in both arms. The temperature was 99 F.; pulse rate, 100 per minute, and respiratory rate, 28 per minute. The white blood cell count was 16,650 per cubic millimeter.

A roentgenogram of the chest disclosed decided subcutaneous emphysema, a left pneumothorax, and partial collapse of the upper two thirds of the left lung. The diaphragm was depressed bilaterally. There was a shift of the heart, trachea and mediastinum to the right. A thin layer of mediastinal air was present in the region of the aortic knob

Two hours after admission, the patient's condition appeared critical. He was anxious and his cyanosis and dyspnea had increased greatly. The subcutaneous emphysema had spread noticeably. Both eyelids were swollen sufficiently to prevent opening, and the skin over the suprasternal notch was rather tense. He was taken to the operating room for mediastinotomy.

With local anesthesia, a linear incision was made in the lower portion of the midline of the neck which extended from the inferior border of the thyroid cartilage to the manubrium sterni. The first layer of deep fascia was incised. In the lower portion of the neck, where this splits to encase the manubrium, an incision was made in the posterior leaf which gave access to the superior mediastinum. At this level air bubbled freely into the incision. Drainage was facilitated by gentle digital separation in both lateral directions and inferiorly into the superior mediastinum for a distance of 1 inch (2.54 cm.). The pretracheal fascia was bulging moderately with trapped air, so it also was incised in the vertical axis below the thyroid isthmus, allowing retained air to escape. The wound was left open, with the raw edges loosely covered with petrolatum gauze, and a light dressing of sterile gauze. Improvement of the dyspnea and cyanosis was immediate. The eyelids were aspirated with a 20 gage needle. On return to the ward the pulse rate had slowed to 84 per minute and respirations to 22 per minute.

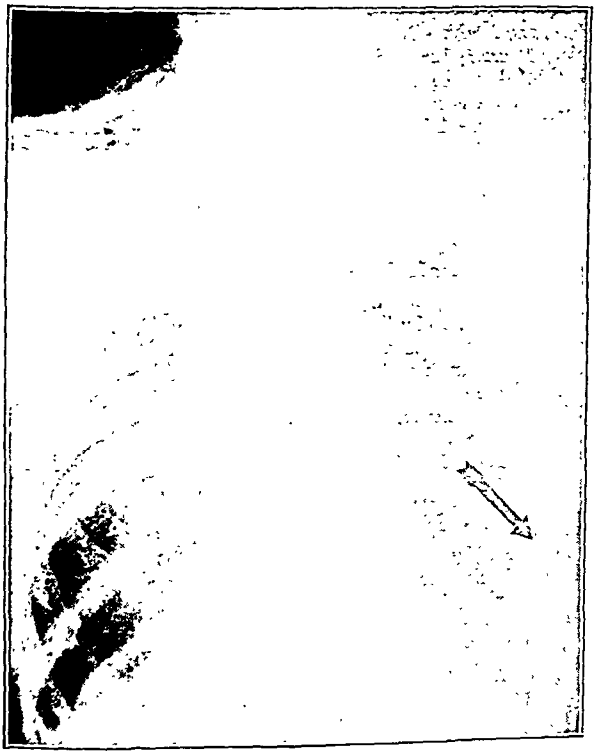

Fig. 1.—Arrow indicates pneumothorax.

After operation, penicillin was given as a preventive measure. The patient was kept in an oxygen tent for eight hours. On the first postoperative day the temperature rose to 100 F. and on the second day to 101 F. On the third postoperative day the penicillin dosage was increased from 30,000 to 50,000 units every three hours. When this proved ineffectual, sulfadiazine was given. The temperature then gradually subsided to normal. The patient's general condition steadily improved, and except for a recurrence of low grade fever convalescence was uneventful. The leukocyte count subsided gradually and three weeks after admission was 6,550 per cubic millimeter. Serial roentgenograms revealed rapid absorption of the pneumothorax, emphysema and the bilateral pleural effusions which developed after admission. The operative wound remained free of evident infection and gradually healed, leaving a normal-sized scar.

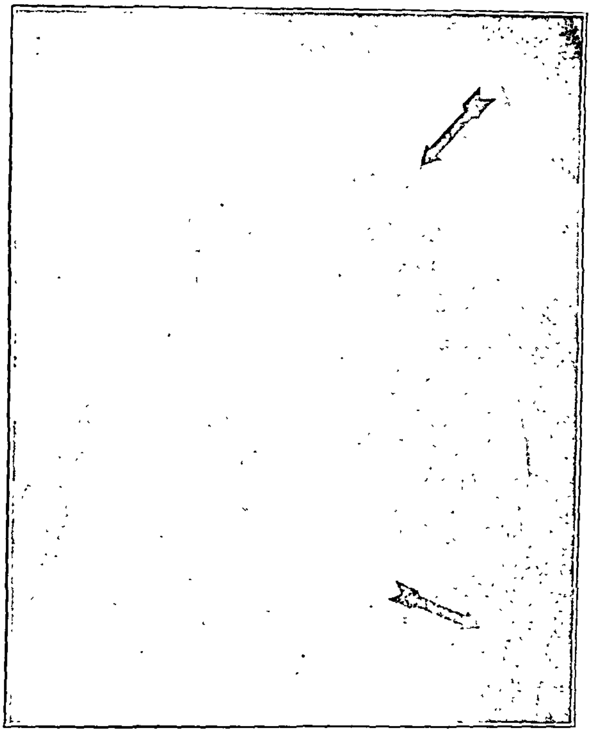

Fig. 2.—Oblique view. Arrows indicate pneumothorax.

COMMENT

This case presents the problem of severe spontaneous mediastinal emphysema with rapidly progressing respiratory and circulatory embarrassment. Pneumothorax causing 30 per cent collapse of the upper two thirds of the left lung was also present but was considered a minimal factor in the symptoms. Mediastinotomy was performed because of the increasing gravity of the patient's condition.

Suprasternal incision, either vertical or horizontal, is the operation of choice. It is our opinion that the vertical incision is more desirable, since it offers less opportunity for wound edges to adhere or for soft tissues to collapse into the wound, thus promoting elimination of air over a longer period of time. Through such an incision blunt dissection of the lateral fascial planes is more easily accomplished. The main disadvantage to a vertical incision is cosmetic, for the resultant scar is larger and is at right angles to the normal lines of skin tension.

SUMMARY

A case of spontaneous mediastinal emphysema requiring mediastinotomy is presented. The clinical picture, diagnosis and management are discussed.

SICKLE CELL DISEASE WITH SEVERE HEMATURIA SIMULATING RENAL NEOPLASM

MARTIN S. ABEL, M.D.
and
CHESTER R. BROWN, M.D.
New York

Since Herrick's first reported case,[1] sickle cell disease has become a well described clinical and pathologic entity. The usual renal manifestations are of minor importance until late in the disease. Traces of albumin or urobilin or a few casts are found in the urine in some cases; in others the urine is essentially normal.[2]

The lesions in the kidneys, as elsewhere, stem from the fundamental tendency of the abnormally shaped erythrocytes to become blocked up in the small arterioles and capillaries. Early in the disease, renal sections exhibit vascular stasis and congestion. Later, after multiple small thromboses and infarctions, the kidneys show more or less extensive fibrosis with deposition of blood pigments.[2c] As more and more glomeruli are destroyed, renal function deteriorates and there may be terminal uremia.[3]

We could find only one report in the literature in which gross hematuria was a prominent feature of the disease: Bauer[4] reported the case of a 10 year old Negro girl who died of massive necrosis of the renal cortex caused by impaction of sickled cells in the small renal vessels. A patient of Murphy and Shapiro,[3] who died of renal insufficiency, evidenced definite hematuria on only one occasion. Yater[5] and Diggs[6] have not encountered gross hematuria in their wide experience with sickle cell anemia. A few red cells were occasionally seen in the urine of their patients, apparently associated with acute episodes of nephritis or small infarcts.

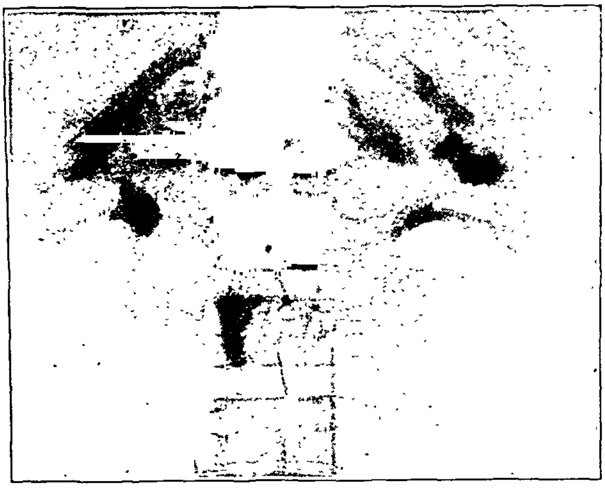

Fig. 1.—Retrograde pyelogram showing filling defect in the left renal pelvis and the upper calyx. This defect was present and unchanged in three pyelograms taken over a period of five weeks.

We encountered a patient presenting severe hematuria, with deformity of the renal pelvis simulating a pelvic tumor. Nephrectomy was performed.

REPORT OF CASE

W. M., a Negro soldier aged [illegible], was admitted to a United States Army General Hospital Dec. 4, 1942 with chief complaints of sore throat and pain in the chest. The patient had also had sudden gross hematuria in August 1942, unaccompanied by pain, dysuria, nocturia or polyuria. His urine had remained "dark" thereafter. The patient had been a railroad worker prior to entry into service and had had no severe illnesses or operations. No history of use of drugs was elicited.

Physical Examination.—The patient was a well developed, robust Negro with mild pharyngitis and bronchitis. His temperature was 98.2 F. and his blood pressure 130 systolic and 70 diastolic. Neither kidney was palpable. There was no lumbar or costovertebral angle tenderness. There were no other significant findings.

Laboratory Studies.—The blood count showed 4,000,000 red blood cells, 81 per cent hemoglobin and 8,500 white blood cells, with normal differential count. The chemistry of the blood was within normal limits. The Van den Bergh reaction was negative. The icteric index was 4. The urine was grossly bloody and contained many red and white blood cells on twenty-five examinations. After nephrectomy on March 12, 1943, repeated moist sealed drop preparations failed to reveal any sickling of red blood cells.

Roentgen Studies.—Chest, Dec. 5, 1942: The heart and lungs were within normal limits. In a survey roentgenogram of the abdomen on December 24 no radio-opaque calculi were noted. The right kidney was normal in size, shape and position. The left kidney was obscured by gas in the colon. An intravenous pyelogram on Feb. 3, 1943 showed incomplete filling of the middle and upper major calyces on the left. In a retrograde pyelogram on February 24 (fig. 1), the pelvis, calyces and ureter on the right appeared entirely normal. There was a filling defect on the left affecting the upper calyx and the superior portion of the pelvis. In a second retrograde pyelogram, on March 8, the filling defect on the left was seen unchanged from its condition on February 24. The possibility of tumor of the left renal pelvis was considered.

Progress Notes.—On January 5 the patient had a severe, persistent cramplike pain in the left costovertebral angle accompanied by severe hematuria. Cystoscopic examinations on February 24 and March 8 revealed grossly bloody urine coming from the left ureteral orifice.

On March 12, in consideration of the roentgen observations and the persistent hematuria, with and without pain, a left nephrectomy was performed. The preoperative diagnosis was renal neoplasm.

The patient was discharged on April 14 after an uneventful convalescence, completely asymptomatic.

Report on Surgical Specimen.—Gross Examination: The kidney measured 10 by 7 by 6 cm. The capsule stripped easily. The cut surface of the cortex was smooth. No unusual changes were noted other than numerous hemorrhages into the mucosal surface of the pelvis. No neoplasm was seen.

Microscopic Examination: There were numerous sickled erythrocytes in all the renal arterioles. The vessels of the pelvis were considerably dilated and filled with sickled and agglutinated red blood cells. A few vessels near the mucosal surface of the pelvis showed partially necrotic walls which were traversed and surrounded by masses of the sickled erythrocytes (fig. 2). The other parts of the kidney showed no unusual changes except for occasional organized thrombi within arterioles.

COMMENT

The clinical aspects of this case presented several unusual features: First, the presence of localized lumbar pain unaccompanied by other symptoms of sickle cell disease is most unusual. The patient of Murphy and Shapiro,[3] dying of uremia caused by multiple capillary infarcts in the kidneys, presented no signs or symptoms referable to the kidney until late in the disease, and never exhibited the specific lumbar pain and tenderness experienced by our patient. Unfortunately Bauer[4] did not report the clinical aspects of his case with renal necrosis. During several months' observation, our patient never displayed the usual manifestations of sickle cell disease.

The roentgenologic and clinical diagnosis of renal tumor is worthy of note. The filling defect persisted unchanged for at least a month and was presumably caused by a blood clot. In the absence of a history of trauma or a demonstrable cause of bleeding, renal pelvic tumor was diagnosed. The intermittent pain was probably caused by detached bits of clot causing transient ureteral obstruction.

[6] Diggs, L. W.: Personal communication to the author.

Finally, we should like to call attention to the absence of hemolytic crises and anemia in our patient. At no time was there a pronounced anemia, and the mild secondary anemia could be easily explained by the evident hematuria. Urobilin was never demonstrated in the urine.

Our inability to demonstrate the sickling tendency in the peripheral blood despite the presence of large numbers of sickled erythrocytes in the kidney sections is most unusual. The reverse is often true, that sickled cells cannot be demonstrated in tissue section even though evident in samples of the peripheral blood.[7] Wintrobe[8] expressed the opinion that decreased oxygen tension may be the factor that causes both the corpuscular distortion and the hemolytic crises in patients with sickle cell disease. Sickle cells are not regularly found in the circulation of nonanemic patients with sickle cell disease. If anoxia is the important factor, we may conjecture that for some obscure cause a purely local decrease in oxygen tension was attained only in the left kidney sufficient to make manifest the latent sickling tendency and bring about the unfortunate sequelae.

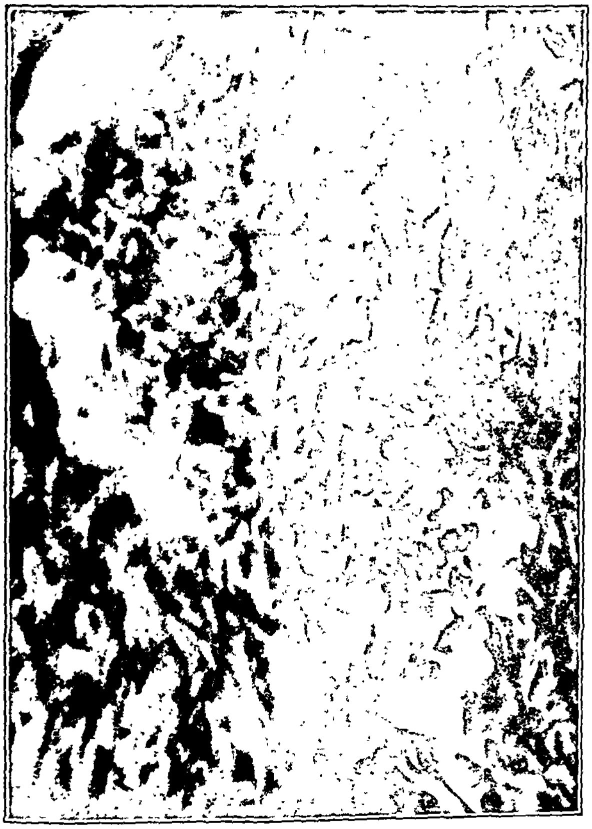

Fig. 2.—Section of left kidney near pelvis, reproduced from a high power photomicrograph showing a necrotic vessel with numerous sickled red blood cells within the lumen, in the wall and outside the vessel.

SUMMARY

A case history has been presented of a patient with extensive necrosis of the renal pelvis caused by obstruction of renal vessels by sickled red blood cells. There was severe hematuria and lumbar pain and deformity of the renal pelvis. The case was unusual because the findings led to an erroneous diagnosis of renal tumor and because there was no evidence to suggest the diagnosis of sickle cell disease prior to nephrectomy.

Council on Physical Medicine

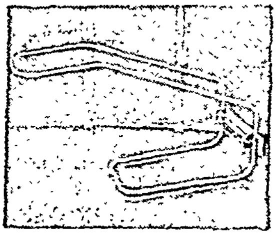
The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

VALVERDE VASCULATOR (BAKER) ACCEPTABLE

Manufacturer: Valverde Laboratories, 252 Lafayette Street, New York.

The Valverde Vasculator is a device for holding the bedclothes up out of contact with a patient's lower extremities while maintaining a thermostatically controlled degree of warmth in the space or tent so formed. Its essential parts are (1) a strong framework of curved, chromium-plated steel tubing and (2) a pair of long, tubular, incandescent lights controlled by a thermostat.

Three features distinguish this apparatus from the conventional baker or heat cradle. One is the strength and simplicity of its design. The second is the roominess of the space under it, which permits the patient to draw his feet up occasionally by raising his knees and also permits attendants an unobstructed view of either extremity on raising the bedclothes. The third is the thermostatic control, which is generally set at 94 F. (34.5 C.).



Valverde Vasculator.

The investigator for the Council reported the apparatus to be of good workmanship. To turn off the lights it is necessary to pull out the plug. The temperature control and metal guards about the two heating elements greatly reduce the danger of burns to the patient.

The Council on Physical Medicine voted to include the Valverde Vasculator in its list of accepted devices.

DREAM SUNLAMP ACCEPTABLE

Manufacturer: Hytron Radio & Electronics Corporation, 76 Lafayette Street, Salem, Mass.

Distributor: Associated Merchandising Corporation, 1440 Broadway, New York 18.

The Dream Sunlamp is identical with the Hytron Sunlamp Type A and similar in construction to the General Electric and Westinghouse lamps of Type RS. It contains a mercury arc tube and ballast coils. The mercury arc tube contains mercury, a starting coil and electrodes. The ballast coils consist of tungsten filaments which limit the current passing through the mercury arc tube. The ballast coils become heated and then radiate infrared and visible light, while the mercury arc tube radiates ultraviolet. The outer conical glass bulb, or glass container, enclosing the sealed space in which lie the mercury arc tube and ballast coils, is made of a type of glass called "Corning 776," which in proper thickness cuts off sharply the transmission of ultraviolet wavelengths below 2,800 angstroms. The inside of the conical part of the bulb is coated with aluminum to form a reflector.

The statements of the firm regarding the exposure needed to produce erythema have been verified by the Council. For initial applications the recommended exposure is a maximum of four minutes at a distance not less than 61 cm. (24 inches).

The firm states that: "The name 'Dream' is a copyrighted trade mark used in connection with a full line of home appliances."

The Council on Physical Medicine voted to include the Dream Sunlamp distributed by the Associated Merchandising Corporation in its list of accepted devices.

SATURDAY, FEBRUARY 28, 1948

IS THERE A SHORTAGE OF PHYSICIANS?

The pronouncement by Dr. Thomas Parran, surgeon general of the U. S. Public Health Service,[1] that the country is faced with a shortage of 30,000 to 50,000 physicians by 1960 has recently been reemphasized by the federal security administrator, Mr. Oscar Ewing. Many government officials, as well as the public, have been led to believe that urgent measures are required to prevent a grave shortage of medical care. Alarm is unwarranted and unjustified. Actually the number of physicians is increasing at a relatively more rapid rate than is the general population. Ten years ago the statistics indicated one active physician for every 800 persons in this country; at present there is one physician for every 760 persons; by 1960 there will be one physician for every 700 persons or fewer. More physicians are currently being trained in this country than at any time in our history. All indications point to a still further increase in the number of physicians graduated each year.

During the period 1920 to 1939 the average number of physicians graduated annually in this country was 4,256. For the eight year period 1940 to 1947 when, due to the accelerated program, nine classes were graduated, the average size of the graduating classes was 5,379. Based on the present capacity of the medical schools, the average number of physicians who will be graduated each year for the next twelve years can be conservatively estimated at 5,500; a considerably larger number may actually be anticipated as a result of expansions that are already under way. The annual production of physicians is now approximately 1,250, or about 30 per cent greater than the average annual production during the period 1920 to 1939.

In estimating a shortage of 30,000 physicians by 1960 Dr. Parran made the incorrect assumption that only 111,000 physicians would be graduated during the period 1940 to 1960 and that 77,000 physicians would die or retire during the same years. A strange error was the subtraction of certain physicians twice from the ranks of those active, once when they retired and a second time when they died. After correcting for these errors and the reduced requirements of the government services, the Public Health Service by inference, but not explicitly, revised downward its estimated shortage of physicians from 30,000 to 20,000.[2] A deficit of 20,000 physicians in 1960 would be less than 9 per cent of the total force of physicians who will be active on that date under the current rate of production.

In reaching an anticipated shortage of 55,000 physicians by 1960 the Public Health Service[2] took the twelve states with the highest ratio of physicians to population and calculated the additional number of physicians needed to bring the remaining thirty-six states up to the average of the upper twelve. This exercise in arithmetic makes the doubtful assumption that the twelve states used as a standard do not have more physicians than they actually need to provide their residents with adequate medical care. A significant number of the physicians in the twelve states with the highest ratio of physicians to population hold teaching, research and administrative positions that do not exist and for which there is no need in the other thirty-six states.

Even Dr. Parran's lower estimate of a deficit of 20,000 physicians used as a yardstick concepts of medical service that are not realistic in terms of what the nation now, or in the period under consideration, is likely to demand or support. If the needs for additional physicians in certain categories listed by the Public Health Service were to be met, the need for physicians in other situations would be appreciably lessened. The employment of an additional 13,000 physicians by the federal services, the employment of an additional 5,000 physicians in full time local health departments and new mental and tuberculosis hospitals, and the appointment of an additional 16,000 specialists to the staffs of new general hospitals would probably decrease considerably the need for physicians otherwise required to provide medical service.

Associated with the publicity about the shortage of physicians have been proposals which would force our medical schools to adopt measures that would impair the quality of medical education. Thus the spokesman for the Public Health Service said that the country would need to increase its present output of physicians by 50 per cent or more during the intervening years to meet the deficit anticipated by 1960. Such a move could be accomplished only by a tremendous lowering of the standards of medical education that have been developed for the protection of the public during the past forty years. Medical schools in this country are now accepting the maximum number of students that can be trained with the personnel and facilities available.

---

[1] Parran, T.: J. A. M. A. **133:** 1047-1049 (April 12) 1947.

[2] Parran, T.: J. A. Am. M. Coll. **23:** 18, 1948.

Facilities for providing a high quality of medical education cannot be developed overnight. Substandard medical schools have now almost completely disappeared from the medical scene in this country; any move that would encourage their reappearance must be condemned. The facilities for medical education in this country are undergoing a definite, well ordered expansion. Four new four year schools have been fully developed during the past few years; two more, the University of Washington and the University of California at Los Angeles, are in the process of development; several of the schools of the basic medical sciences are making definite plans to become four year schools, and the establishment of entirely new schools is under active consideration in a number of states. Such expansions, based on sound planning, will satisfactorily eliminate any actual shortage of physicians that may be imminent.

Advocates of radical proposals which would deteriorate standards of medical education do not hesitate to imply that the American Medical Association for economic reasons limits the production of physicians in this country. This charge is entirely without basis! The Association has never sought to limit the number of properly conducted medical schools in this country. Even if the Association desired to reduce either the schools or the number of students it could not do so. Through the Council on Medical Education and Hospitals, the Association has always placed its support and assistance at the service of any responsible group interested in developing a new medical school. On the infrequent occasions when the Association has made recommendations to any school concerning the size of its enrolment, the recommendation has been based wholly on a concern that the school not attempt to train more students than it could properly handle. No private or official body has the power to control the production of physicians in the United States. An increased production of physicians will require enterprise in establishing medical schools and the provision of sufficient funds to supply a sound educational program.

High standards of medical education are fundamental to good medical care. The standards of medical education in this country have been raised from deplorable mediocrity to the point where they are the best in the world. The Public Health Service is concerned with the health of our nation. How can such an agency support a movement that could result in medical care of inferior quality? Conceivably the statistics and estimates regarding the number of physicians needed are being abused for political purposes, exactly as were the selective service statistics until the clear analyses by Freedman became available. The United States Public Health Service should restudy its figures and its estimates, and if its estimates of any impending deficit of physicians can be reduced, it should inform the public that any shortage that may reasonably be forecast is not critical to the nation's health. Let them tell the people that the medical schools of the United States now produce the best trained physicians to be found anywhere in the world. Far more will be lost than gained if the standards of medical education are sacrificed to an abrupt and unnecessary increase in the output of physicians.

The Public Health Service might well join with other groups that have at least an equal concern for the nation's health in the conduct of a calm, scientific appraisal of the nation's needs for physicians and how these needs may best be met without impairing the quality of medical education and medical care. Such a study could serve as the basis for an effort supported by all concerned with the training and production of physicians to develop a sound and effective program fitted to the actual needs of the country. Such an effort is difficult as long as propagandists continue needlessly to alarm the public and to make medical education the center of disagreeable and wholly unnecessary controversy.

THE SIGNIFICANCE OF URINARY COPROPORPHYRINS

The porphyrins include many complex chemical compounds of fundamental importance in living organisms. Biologic substances that contain porphyrin derivatives include hemoglobin and similar respiratory pigments, the cytochromes, the enzyme catalase and chlorophyll in plants. Porphyrins occur in plant and animal tissues, including those of man. Coproporphyrin[1] was first found in the feces of a now famous case of congenital porphyria, Petry, by Hans Fischer[2] in 1915. Because the porphyrin was present almost entirely in feces, Fischer unfortunately called the substance "coproporphyrin." Subsequently, coproporphyrin was found in the urine in relatively large amounts in certain conditions. For the same reason, Fischer applied the name "uroporphyrin" to a porphyrin found in the urine in his case of congenital porphyria. Later work also demonstrated the presence of this porphyrin in the feces in a variety of conditions. Continuing his work on the porphyrins excreted in congenital porphyria, Fischer finally succeeded in crystallizing both coproporphyrin and uroporphyrin. Then in a series of brilliant chemical studies, for which Fischer was awarded the Nobel Prize in 1930, he demonstrated that these two porphyrins differed in chemical structure from those found in the urine and feces of normal subjects. The substances were isomers differing only in the positions of two small portions of the molecule. Fischer gave the name type 1 to the porphyrin found in cases of congenital porphyria and type 3 to that found in the normal person. Subsequently, this has been referred to as the "dualism" of the porphyrins.

---

[1] Watson, C. J., and Larson, E. A.: The Urinary Coproporphyrins in Health and Disease, Physiol. Rev. **27**: 478, 1947.

[2] Fischer, H.: Ueber das Kotporphyrin. II. Mitteilung über das Urinporphyrin, Ztschr. f. physiol. Chem. **96**: 148, 1915.

Studies since Fischer's classic work have verified the presence of coproporphyrin types 1 and 3 (as well as uroporphyrin) in the urine and feces and have established to some extent the amounts and types in a variety of conditions. Later, in normal human subjects, Watson and his co-workers at the University of Minnesota[1] have found that 14 to 99 micrograms of coproporphyrin is excreted in the urine in twenty-four hours, approximately 80 per cent being the type 1 isomer and 20 per cent the type 3. This amount and the ratio of the two types of porphyrins are considerably altered in certain pathologic conditions. In certain diseases of the liver, including hepatitis with jaundice, cirrhosis and mechanical jaundice, the amount of urinary coproporphyrin may be definitely increased. The increase may be a result of impaired excretory hepatic function, since some coproporphyrin is excreted normally in the bile.[3] An increased excretion of coproporphyrin in the urine is also found in chronic alcoholic addicts; in infectious diseases including pneumonia, pulmonary abscess and poliomyelitis; in pellagra, and in poisoning from lead, arsenic or certain drugs including sulfonamide compounds, acetanilid, phenacetin, acetylsalicylic acid, ether, paraldehyde, chloralhydrate and morphine. Inconstant increases in urinary coproporphyrin excretion have been demonstrated in pernicious anemia, aplastic anemia, hemolytic anemia and leukemia. The porphyrin excreted in the urine in increased amounts in the foregoing conditions appears to be type 3. This is particularly true in lead poisoning, in which as much as 8 milligrams of coproporphyrin, predominantly type 3, have been found in twenty-four hour samples of urine.

In addition to the pathologic states mentioned, large increases in urinary coproporphyrin are found in the "porphyrias." As mentioned previously, excessive amounts of type 1 coproporphyrin are found in the urine of cases of congenital (light sensitive) porphyria. In so-called acute intermittent porphyria, which is characterized by abdominal or nervous manifestations, the type 3 isomer appears to predominate. As much as 2,582 micrograms of coproporphyrin has been reported in the urine in twenty-four hours in 1 case of acute porphyria. Even larger amounts of uroporphyrin, as much as 147 mg., have been isolated from daily samples of urine.

An explanation of the increase in urinary coproporphyrin in the foregoing clinical conditions is difficult. In the porphyrias the explanation appears to be that there is some inborn error of metabolism, which results in an increased synthesis and, hence, in urinary excretion of coproporphyrin. In lead poisoning, and perhaps in other toxic conditions, the normal combination of protoporphyrin with iron to form hemoglobin may be blocked[4] by lead; the nonutilized porphyrin is then converted to coproporphyrin and excreted in the urine. In hepatic diseases the explanation of the increased coproporphyrinuria may be, as previously mentioned, an impairment of the hepatic excretory function.

Although there is much information available regarding the amounts and types of coproporphyrin excreted in varying conditions, the mode of formation and exact physiologic role of this substance is poorly understood. The significance of the coproporphyrin found in brain and nervous tissue,[5] for example, is yet to be determined.

BRITISH PHYSICIANS REJECT NATIONALIZED MEDICINE

In a plebiscite conducted by the British Medical Association 86 per cent of British physicians voted against working for the universal free medical service scheme that has been scheduled to take effect on July 5. Of course the scheme is not really free, since every tax payer in England contributes toward its support. If the physicians stand firm in their refusal to work, the British government would have only 3,560 general practitioners and 971 consultants to provide the National Health Service for about 47,000,000 people. In the plebiscite 89.5 per cent of British physicians disapproved the National Health Service Act in its present form. This vote was 40,814 to 4,735. As has already been said, 86 per cent voted against accepting the service, the vote being 24,340 to 4,084. Of these, 84 per cent said that they would conform with the major decision and would not accept service. This vote was 24,066 to 4,495. The ballots were sent to more than 56,000 doctors, and 82 per cent were returned. The British physicians are not striking against the sick; they will care for their patients but will not accept payment from the government.

Now the British Medical Association proposes to present the results of the ballot to its representative body, which will meet at the headquarters of the British Medical Association on March 17. In Great Britain a small group of physicians opposed the combat with the government and one organized group—the Socialist Medical Association—has been giving aid and comfort to the Minister of Health and his satellites by asserting that most general practitioners will eventually be anxious to join the service on account of the generous financial terms that the government has offered.

[5] Kluver, H.: On Naturally Occurring Porphyrins in the Central Nervous System, Science **99:** 482, 1944.

The British Medical Association opposes the National Health Service Act as the first and irrevocable step toward a whole time state medical service. In Great Britain, as in this country, the national medical care plan is offered as a health service instead of what it actually is—a system which would eventually bring every physician into government employment. The *British Medical Journal* has inspired British physicians to stand firm in their opposition to such enslavement. In an editorial published January 17 the *British Medical Journal* says:

> "Doctors are not business men. They do not form a class whose money comes to them by heredity. They work hard—probably harder and certainly for longer hours than any other section of the community. They are subject to great strain and risk of ill health. The love of their work makes them put up with much that no other group of workers would tolerate. Next to their work what they most prize is freedom—freedom to practice what they are taught and to carve out a career by hard endeavor. In Britain this freedom is secured by the ownership of general practices and by voluntary service in hospitals. This freedom is now being undermined. What medical men most fear is this loss of freedom. By standing firm they can retain it."

Current Comment

SELECTIVE SERVICE STATISTICS

Before the senatorial committee hearing on proposed health legislation in Washington, D. C., and again at the recent meeting of the National Conference on Rural Health in Chicago, Dr. Maurice H. Friedman discussed the high incidence of medical defects noted in the selective service statistics. In many cases claims as to the need of extension of medical care based on these statistics have been unjustified. A workman falls into a machine and sustains a crushing injury of the arm; good medical and surgical care in this instance preserves his life, even though amputation becomes necessary. This patient eventually appears in selective service statistics as a medical defective. Patients may have perforated ear drums following incision of the drum for otitis media. In the presulfonamide, prepenicillin period, incision of the drum for drainage was good medical care. Cases of rheumatic heart disease, diabetes and thousands of other cases in which good medical care preserved lives of patients who might otherwise have died are reflected eventually in the statistics. Had all these patients been allowed to die, statistics regarding numbers of medical defectives would be considerably improved. In the war years, 1942 to 1945, both infant mortality and maternal mortality rates improved. During this period approximately one third of all physicians in the United States were in military service or otherwise unavailable to the civilian population. Should this be interpreted to mean that there are too many physicians in the United States? Many similar interpretations can be placed superficially on draft statistics. Dr. Friedman warns that thorough study is still necessary before the true interpretations can be placed on the statistics.

PHENYLPYRUVIC OLIGOPHRENIA

In 1934 Fölling[1] reported the discovery of phenylpyruvic acid in the urine of certain feebleminded patients, apparently the result of incomplete metabolism of phenylalanine, an amino acid commonly found in food proteins. Indeed, further studies[2] showed that the output of this abnormal metabolite varied directly with the level of protein in the diet and that the feeding of either of the optical isomers of phenylalanine resulted in an augmented excretion of phenylpyruvic acid. In the same conditions the concentration of phenylalanine itself is increased in the blood and spinal fluid.[3] The incidence of this metabolic error in a large population of feebleminded persons is about 0.5 per cent,[4] and it appears to be hereditary.[5] Blond hair, blue eyes, patchy eczema and rather heavy musculature with increased tone and with tremor are physical characteristics frequently noted in these patients with phenylpyruvic oligophrenia. Deviation from the normal does not occur in the amino acid content of the tissues in this condition.[6] The benzene ring is notably difficult to oxidize in the body, and it frequently has been used experimentally to label compounds whose metabolic fate is being studied. Disease such as tyrosinosis and alkaptonuria are classic examples of errors of metabolism in which the phenyl group in ordinary amino acids is involved. Also, experimentally, aromatic metabolites of phenylalanine can be demonstrated under certain conditions in rats on a thiamine-deficient diet and in guinea pigs when ascorbic acid is lacking in the ration. However, from the available evidence it appears that the metabolic disturbance in phenylpyruvic oligophrenia is distinct from that hitherto induced in experimental animals. Jervis[7] believes that the metabolic defect in these mental patients resides in a failure to attach a hydroxyl group to the benzene ring in phenylalanine, which would take place under normal conditions and thus carry the metabolism through tyrosine and on to carbon dioxide and water. The close correlation between a rather specific chemical deviation and mental abnormality in certain feebleminded patients raises again the hope of demonstrating similar relationships in other types of mental disease. Once this is done, the way may be open to more productive therapy in these situations.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Feb. 26, 1948.

President Truman Announces Appointment of Dr. Scheele

As noted in THE JOURNAL last week, President Truman announced that Dr. Leonard A. Scheele, assistant surgeon general of the U. S. Public Health Service and director of the National Cancer Institute, has been appointed surgeon general. He will succeed Surgeon General Thomas Parran under the policy of the U. S. Public Health Service whereby the surgeon generalship is rotated to maintain high morale in the service. Dr. Parran will continue as this country's representative on the World Health Organization, and he will doubtless officiate to some extent as a representative at large of the service on world health matters. Oscar R. Ewing, federal security administrator, commented that "if you don't rotate the jobs you kill the ambition of men in the service." Appointment of Dr. Scheele conforms with the service's policy of avoiding patronage appointments.

Medical Chief Comments on Retirement Systems

During House Armed Services Subcommittee hearings on the armed forces' retirement pension systems, Rear Admiral Clifford A. Swanson, Navy Surgeon General, stated that the fact that a retired officer was approved for life insurance or was able to earn a good living in private industry would not mean that the Navy was wrong in giving him a disability retirement. He said: "After all, an amputee with good life expectancy is likely to be an excellent insurance risk, and a blind man can make good money as a musician. In both cases the men would not be acceptable for active Navy duty."

Medical Legislation

STATE LEGISLATION

Kentucky

Bills Introduced—H. 232 proposes that no hospital shall, on account of race, deny any physician the right to practice in the institution, or deny any student the right to receive hospitalization in the institution or deny any student the right to receive postgraduate or inservice instruction or training in the institution. S. 162 proposes to prohibit the handling, sale and distribution of barbiturates except on the written prescription of a practitioner licensed to prescribe and administer barbiturates, with certain stated requirements relating to pharmacists and wholesale dealers in the drug. S. 167 proposes the enactment of a licensing law for hospitals, health centers and nursing homes. S. 170 proposes to authorize the board of trustees of the University of Kentucky to establish a college of medicine and surgery in connection with the University.

Massachusetts

Bill Introduced.—H. 1748 proposes, on the basis of an initiative petition, to authorize physicians to provide medical contraceptive care to married women for the protection of life or health.

Mississippi

Bills Introduced.—H. 351 proposes the enactment of a workmen's compensation law. H. 386 proposes the appropriation of $510,000 to the state medical education board for the purpose of carrying out the provisions of the law relating to medical scholarships and loans. H. 423 proposes the creation of a four year medical school as a department of the University of Mississippi, which shall be operated as a class A medical school in accordance with the Council on Medical Education of the American Medical Association. S. 187 proposes an act to provide for the treatment and/or assistance and diagnosis of patients having cancer or suspected of having cancer.

Rhode Island

Bill Introduced.—H. 658 proposes an act to extend and strengthen the mental health services in the state and proposes to designate the state department of social welfare as the agency to cooperate with the federal government in this regard.

South Carolina

Bills Introduced.—H. 1104 proposes to authorize the deduction for state income tax purposes of expenses of hospitalization, medical service and medicine paid on behalf of the taxpayer or any dependent. H. 1190 proposes a bill to create and maintain county boards of health, to prescribe their duties, and so forth.

Coming Medical Meetings

Alabama, Medical Association of the State of, Mobile, April 15-17. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association of Anatomists, Madison, Wis., April 21-23. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Industrial Physicians and Surgeons, Boston, March 28-April 4. Dr. Frederick W. Slobe, 28 E. Jackson Blvd., Chicago 4, Secretary.

American Association of Pathologists and Bacteriologists, Philadelphia, Jefferson Medical College, March 12-13. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland 6, Secretary.

American Broncho-Esophagological Association, Atlantic City, Chalfonte-Haddon Hall, April 7-8. Dr. Paul H. Holinger, 700 N. Michigan Ave., Chicago 11, Secretary.

American College of Allergists, New York, Hotel Pennsylvania, March 12-14. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary

American College of Physicians, San Francisco, Civic Auditorium, April 19-23. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Secretary.

American Laryngological Association, Hot Springs, Va., April 14-15. Dr. Louis H. Clerf, 1530 Locust St., Philadelphia 2, Secretary.

American Laryngological, Rhinological and Otological Society, Atlantic City, April 7-9. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.

American Orthopsychiatric Association, New York, Hotel Commodore, April 12-14. Nina Ridenour, Ph.D., 1790 Broadway, Rm. 916, New York 19, Secretary.

American Otological Society, Hot Springs, Va., April 12-13. Dr. Gordon D. Hoople, 713 E. Genesee St., Syracuse 2, N. Y, Secretary.

American Physiological Society, Atlantic City, March 15-19. Dr. Maurice Visscher, University of Minnesota, Minneapolis 14, Secretary.

American Society for Experimental Pathology, Atlantic City, March 15. Dr. Frieda S. Robscheit-Robbins, 260 Criddenden Blvd., Rochester 7, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 14-19. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.

Arkansas Medical Society, Little Rock, Robinson Auditorium, April 15-17. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

California Medical Association, San Francisco, April 11-14. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 2-5. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18 Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Federation of American Societies for Experimental Biology, Atlantic City, March 15-19. Dr. William H. Chambers, Medical Division, Army Chemical Center, Maryland, Secretary.

Florida Medical Association, St. Augustine, Ponce de Leon Hotel, April 11-14. Dr. Robert B. McIver, 111 W. Adams St., Jacksonville, Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Louisiana State Medical Society, Monroe, April 12-14. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.

Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 10-12. Dr. H. H. Cummings, 2014 Olds Tower, Lansing 8, Chairman.

Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Exec. Secretary.

New England Dermatological Society, Boston, April 14. Dr. G. Marshall Crawford, 1180 Beacon St., Brookline, Mass., Secretary.

Northern Tri-State Medical Association, Findlay, Ohio, April 13. Dr. Don F. Cameron, 247 W. Berry St., Ft. Wayne, Ind., Secretary.

Ohio State Medical Association, Cincinnati, March 30-April 1. Mr. C. S. Nelson, 79 E. State St., Columbus 15, Secretary.

Oklahoma State Medical Association, Oklahoma City, April 18-22. Mr. Dick Graham, 210 Plaza Court, Oklahoma City, Executive Secretary.

Southeastern Surgical Congress, Hollywood, Fla., Hollywood Beach Hotel, April 5-8. Dr. Benjamin T. Beasley, 45 Edgewood Avenue S. E., Atlanta 3, Ga., Secretary.

Southwest Allergy Forum, Oklahoma City, April 5-6. Dr. Fannie Lou Leney, 1200 N. Walker St., Oklahoma City, Secretary.

Tennessee State Medical Association, Nashville, April 13-14. Dr. W. M. Hardy, 706 Church St., Nashville 3, Secretary.

United States-Mexico Border Public Health Association, Laredo, Texas and Nueva Laredo, Mexico, March 20-22. Dr. M. F. Haralson, U. S. Court House, El Paso, Texas, Secretary.

GOVERNMENT SERVICES

ARMY

TOUR OF INSPECTION BY COMMITTEE ON MEDICAL AND HOSPITAL SERVICES

The Committee on Medical and Hospital Services of the Armed Forces, appointed by Secretary of Defense Forrestal, left Washington, D. C., February 16 to visit medical installations in Florida, Texas, Arizona, California, Washington, Colorado, Missouri and Ohio. The committee, with Dr. Paul R. Hawley, formerly chief medical director of the Veterans Administration, as chairman, was instructed to make a thorough, objective and impartial study of the medical services of the Armed Forces, so that the Secretary of Defense may obtain at the earliest possible date "the maximum degree of coordination, efficiency and economy" in their operation.

The official party includes Major Gen. Raymond W. Bliss, surgeon general of the Army; Rear Admiral C. A. Swanson, surgeon general of the Navy; Major Gen. Malcolm C. Grow, the air surgeon, U. S. Air Force, and Rear Admiral Joel T. Boone (MC), U. S. Navy, executive secretary of the committee. The installations visited and to be visited by the committee, and the dates of the visits, are:

February 17—Pensacola, Fla., Navy Flight Surgeon's School, and Houston, Texas, Naval Hospital.

February 18—San Antonio, Texas, Army General Hospital, Air Force Station Hospital and School of Aviation Medicine.

February 19—El Paso, Texas, Army General Hospital, and Tucson, Ariz., Air Station Hospital.

February 20 and 21—San Diego, Calif., Naval Air Station Dispensary, Naval Hospital, and medical facilities of Naval Training Center, Marine Corps Base and Naval Receiving Station.

February 22—Riverside, Calif., (March Field) Air Station Hospital, and Corona, Calif., Naval Hospital.

February 23—Pasadena, Calif., Army General Hospital, and Long Beach, Calif., Naval Hospital.

February 24—Moffett Field, California, Naval Dispensary.

February 24, 25 and 26—San Francisco, Letterman Army General Hospital, Oakland Naval Hospital, Mare Island Naval Hospital, Army and Navy Medical Supply Depots (Oakland and San Francisco), Hamilton Field Air Force Station Hospital.

February 27—McCord Field, Washington, Fort Lewis Army General Hospital, and Seattle, Sands Point Naval Air Station Dispensary.

February 28—Bremerton, Wash., Naval Hospital

March 1—Denver, Lowry Field Air Force Station Hospital, Fitzsimons Army General Hospital

March 2—St. Louis, Army Medical Supply Depot.

March 2 and 3—Dayton, Ohio, Wright Field Air Force Station Hospital, Air Force Aeromedical Laboratory.

Specific problems which Secretary Forrestal asked the committee to study include: (1) improvement in use of existing hospital facilities; (2) coordination of current plans for construction of any new hospital facilities; (3) methods for improving organization, management and administration in operation of hospital and medical programs; (4) coordination or consolidation of medical research and maximum joint use of research facilities; (5) coordination or consolidation of medical training programs; (6) allocation to one service of responsibility for providing all hospitalization and medical care for all services in certain fields of medicine, and (7) development, to the highest practicable degree, of common standards, practices and procedures with respect to physical and mental requirements for entrance into the service and disability discharges, for preventive medicine and for the organization, administration and operation of hospitals.

The committee is to study these problems and to report its observations, conclusions and recommendations to Secretary Forrestal for his consideration and possible action. The committee has no power to order changes. Among those who accompanied the committee on the tour of medical installations are:

Navy.—Rear Admiral Bertram Groesbeck (MC), chief, Aviation Medicine Division, Bureau of Medicine and Surgery. Rear Admiral C. B. Rault (DC), chief, Dental Division, Bureau of Medicine and Surgery. Capt. J. B. Logue (MC), chief, Personnel Division, Bureau of Medicine and Surgery. Capt. Nellie J. Dewitt (NC), director, Navy Nurse Corps. Lieut. Comdr. A. H. Nelson (MSC), administrative assistant to the Surgeon General of the Navy. Lieut. Harry W. Combs (MSC), Enlisted Personnel Branch, Bureau of Medicine and Surgery. Miss Clare R. Murphy, secretary to the Surgeon General.

Army.—Major Gen. T. L. Smith, D. C., chief, Dental Division, Office of the Surgeon General. Col. M. G. Phillips, chief, Army Nurse Corps. Col. P. I. Robinson, M. C., chief, Personnel Division, Office of the Surgeon General. Col. R. E. Duke, M. C., chief, Education and Training Division, Office of the Surgeon General. Major J. F. Doyle, M. S. C., Assistant Executive Officer, Office of the Surgeon General.

Air.—Col. W. H. Powell Jr., M. C., chief, Professional Division, Office of the Air Surgeon. Col. Daniel Ogle, M. C., surgeon, Air University, Montgomery, Ala.

TEST REACTIONS OF SOLDIERS TO HEAT AND COLD

Army Medical Department researchers have undertaken experiments, with the cooperation of the U. S. Air Force, to determine what might happen to the physical and psychologic well-being of soldiers suddenly transported by air from war climates to extreme arctic cold. Thirty-two Air Force soldiers, selected for high physical and mental capacity from a group of volunteers, have been flown from the semitropic climate of McDill Field, Florida, to a subarctic cold area to the far North.

All the men had been stationed at the Florida post for months and were completely adjusted to that climate. Within less than fifteen hours they were set down amid snow and ice in zero temperatures to set up a bivouac.

For several weeks before leaving Florida they were subjected to practically every physical test known to medical science. These tests ranged from basal metabolic and blood pressure measurements to complete blood chemistry. Sulfur content of red cells, vitamin C content of blood cells and plasma, complete urinalyses, concentration of sex and adrenal hormones and their precursors and analysis of body fats were among the determinations.

When the men arrived at their arctic base the tests were again performed. The objective is to discover the biochemical and physiologic changes which accompany day to day acclimatization to cold and the variation of these changes with individuals. The entire field is one in which there are relatively few scientific data. Much has been discovered in tests under simulated conditions, but much remains to be explored as to psychologic reactions and their effects on physical well-being, reactions known medically as psychosomatic.

At their bivouac the men have been divided into three groups. One group will be fed a ration of about 500 calories a day, only half the average human requirement. Another will receive the equivalent of 1,800 calories a day, about what is required in the Florida climate. The third will receive 5,700 calories, consisting mostly of fats and comparable to the diet of Eskimos and others who dwell in the arctic. Presumably those receiving the high caloric ration will adjust best, but the adjustments of those in the other groups are expected to shed light on the importance of diet in acclimatization.

The technical director of this operation is Dr. Robert E. Johnson of the Army Medical Nutrition Laboratory at Chicago. The party is under the command of Lieut. G. E. Gustafson of the same laboratory. Members of the staff and consultants of the Army Surgeon General are participating.

APPOINTMENTS TO MEDICAL SERVICE CORPS

Monroe E. Freeman, Ph.D., research professor of biochemistry, Massachusetts State College, has resigned and joined the medical service corps in the Army as a major.

Elmer F. Chaffee, M.S., bacteriologist, has resigned from the State Department of Public Health of Idaho and joined the medical service corps as a major. Both of these officers served in the Army overseas during the war.

PUBLIC HEALTH SERVICE

REPORT ON RESULTS OF HILL-BURTON ACT

The U. S. Public Health Service reports that under the Hospital Survey and Construction Act (Hill-Burton Act) as of February 6, one hundred and twenty-four applications for hospital construction have been approved from sixteen states. Of these, one hundred and four are general hospitals, only eleven of which are located in communities of more than ten thousand population. Only forty-one of the hundred and four general hospitals have more than fifty beds. The total cost of approved projects is estimated at about $60,000,000, of which about $18,000,000 will be from federal sources and the remainder from state or local funds.

Forty-nine of the fifty-two states and territories have submitted information indicating their desire to participate in the program. Budgets that provide federal funds to assist in the development of hospital survey and planning have been approved for forty-seven states, while the other five states have not yet requested funds. Forty states have submitted hospital construction plans, thirty-three of which have been approved by the Surgeon General. Legislation authorizing the states to conduct their survey and construction program has been passed or found already sufficient in fifty of the states and territories. Legislation granting authority to license hospitals has been passed or found sufficient in twenty-four states. Eleven states have prior legislation which is sufficient for this program. In six states the legislation appears to be adequate, but the Attorney General will have to issue an opinion supporting that view. In the other eleven states the model legislation was not passed, and it will be necessary for the state to determine that sufficient authority exists or to pass authorizing legislation before minimum standards for maintenance and operation can be issued and enforced. Seven states and one territory—Alabama, Alaska, California, Illinois, Mississippi, New York, North Carolina and Utah—have enacted legislation authorizing allotment of their funds to communities for use in matching federal money for construction.

ECREASE IN TYPHUS IN SOUTHERN STATES

Reported cases of murine typhus decreased 56.4 per cent in two years in nine Southern states, as a result of DDT dusting by state and local health departments, according to preliminary data published in a recent issue of *Public Health Reports.* The Communicable Disease Center of the Public Health Service at Atlanta, Ga., inaugurated the expanded typhus control program in July 1945 by reducing the number of rat ectoparasites. A 10 per cent DDT dust was applied to rat runs, burrows and harborages. Projects were established in the one hundred and twenty-two counties that reported 72.3 per cent of all typhus cases in the nine principal typhus states, or 70.5 per cent of all typhus reported in the United States. In the ten counties with the highest incidence of typhus reported cases dropped from 1,074 in 1944 to 395 in 1946. In all dusted areas reduction of Oriental rat fleas has averaged 84 per cent on the basis of actual flea counts from more than seventeen thousand live rats.

STUDIES ON SCHISTOSOMIASIS

Previously withheld from publication for security reasons, results of research on the blood fluke infection, schistosomiasis, have been released by the U. S. Public Health Service in "Studies on Schistosomiasis," National Institute of Health Bulletin 189. Many of the institute's investigations into this snail-borne disease were conducted at the request of the Surgeon General of the Army. While the disease is not endemic in this country, some military personnel returning from overseas were found to be infected, mostly as a result of exposure in certain islands of the Philippines. Major aspects of the research included: determination of whether domestic snails could serve as intermediate hosts of the three species of human schistosomes and whether treatment of sewage and water could destroy ova and miracidia, and what processes were made effective; development of ointments for chemical impregnation of fabrics against penetration of the larval cercariae, and diagnosis of the disease by serologic and intradermal tests. The two hundred and twelve page bulletin, "Studies on Schistosomiasis," may be purchased through the Superintendent of Documents, Government Printing Office, Washington 25, D. C., at 55 cents a copy.

APPOINTMENTS TO MENTAL HYGIENE DIVISION

The Federal Security Administrator has announced the following appointments to the headquarters staff of the Mental Hygiene Division, U. S. Public Health Service:

Senior Surgeon Seymour D. Vestermark as chief, Training and Standards Section. Dr. Vestermark was formerly executive officer and director of training of the U. S. Public Health Service Hospital, Fort Worth, Texas.

Dr. Jerry W. Carter Jr. as psychologist, Operational Projects Section. Dr. Carter was formerly director of the Wichita Guidance Center, Wichita, Kan.

Dr. Henry D. Sheldon as chief, Institutional Statistics Unit, Statistics and Special Studies Section. Dr. Sheldon was formerly chief of the Institutional Statistics Unit, Bureau of the Census.

The following commissioned officers of the U. S. Public Health Service have been assigned as consultants in mental health to the Public Health Service District Offices:

Surgeon James F. Maddux to District 7, Kansas City, Mo. Surgeon William C. Jenkins Jr. to District 8, Denver. Dr. Maddux and Dr. Jenkins recently took postgraduate training in psychiatry at the Colorado Psychopathic Hospital, Denver.

ANNUAL CENSUS OF MENTAL PATIENTS

The annual census of patients in mental institutions, which has been conducted by the U. S. Bureau of the Census since 1926, has been transferred to the Mental Hygiene Division of the U. S. Public Health Service, as a result of its increased responsibilities under the National Mental Health Act. An Institutional Statistics Unit has been established in the Statistics and Special Studies Section, of which Dr. Charles C. Limburg is acting chief. Dr. Henry D. Sheldon, who has been chief of the Institutional Statistics Unit of the Bureau of the Census, will continue to be chief of the unit on its transfer. In addition to continuing the census of patients in mental hospitals and institutions for epileptics and the mentally defective, plans are now being made to enlarge the census of psychopathic hospitals and psychiatric services in general hospitals and to include a census of mental hygiene clinics operated under federal, state and local government and fraternal and private auspices. Publication of the consolidated annual report, "Patients in Mental Institutions," will be continued by the Public Health Service.

AWARD TO DR. HINGSON

The Junior Chamber of Commerce of the United States has named Dr. R. A. Hingson, surgeon, U. S. Public Health Service, as one of the ten outstanding young men of the nation for 1947 and in ceremonies at Chattanooga, Tenn., January 21, presented to him a gold key as a token of the honor. Dr. Hingson is known especially for his part in developing continuous caudal analgesia for the control of pain in childbirth and in the treatment of eclampsia and peripheral vascular disease. The method has been used in more than half a million deliveries. During the last eight years training classes conducted by Dr. Hingson in the use of this method have been attended by more than 1,500 physicians. At present he is detailed by the Public Health Service to the University of Tennessee College of Medicine, Memphis, where he is codirector of the postgraduate course in anesthesiology and obstetrics. He is a graduate of Emory University School of Medicine, Atlanta, Ga. He has contributed many articles on caudal analgesia to scientific journals and is co-author of a book "Control of Pain in Childbirth." He served during the war in rescue work on a Coast Guard Cutter and in patrol and convoy duty for the Navy.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: *such as relate to society activities, new hospitals, education and public health.* Programs should be received at least two weeks before the date of meeting.)

COLORADO

Dr. Waring Resigns as Administrator.—Dr. James J. Waring has resigned as the administrative head of the Department of Medicine of the University of Colorado School of Medicine, Denver. He will continue with the school as a full time teaching professor. The new departmental head has not yet been appointed.

Annual Midwinter Postgraduate Clinics.—The thirteenth annual Midwinter Postgraduate Clinics, sponsored by the Colorado State Medical Society, will be held March 3-5 in Denver. Guest speakers will be: Paul D. White, Boston, cardiology; Gershom J. Thompson, Rochester, Minnesota, urology; Everett D. Plass, Iowa City, obstetrics and gynecology; William B. Parsons, New York, surgery; William C. Menninger, Topeka, Kan., psychiatry; William R. Lovelace II, Albuquerque, N. Mex., surgery; John R. Lindsay, Chicago, otolaryngology; Robert L. Jackson, Iowa City, pediatrics, and Franklin M. Hanger, New York, internal medicine.

GEORGIA

Dr. Nonidez Dies.—José F. Nonidez, Sc.D., professor of microscopic anatomy of the University of Georgia School of Medicine, Augusta, died recently, aged 55, of coronary thrombosis. Dr. Nonidez was formerly research associate in the Department of Experimental Evolution at Cold Spring Harbor, N. Y.

Annual Meeting of Ophthalmologists.—The Georgia Society of Ophthalmology and Otolaryngology will hold its annual meeting at the Fulton County Academy of Medicine, Atlanta, March 5-6. The lecturers include Drs. Bennett Y. Alvis, St. Louis; Arthur J. Bedell, Albany; Ramon Castroviejo, New York; J. Brown Farrior, New Orleans; French K. Hansel, St. Louis; J. Elliott Scarborough Jr., Atlanta. There will be no registration fee for out of state guests attending the meeting.

ILLINOIS

Measles Epidemic.—For the week ending February 7 measles cases in the state totaled 1,900 or 108 more than in the preceding week. The total number of cases to February 13 was 7,738 compared with 112 in the corresponding period last year, according to the state health department.

Mental Hygiene Meeting.—The Illinois Society for Mental Hygiene will hold its annual meeting March 18 at the La Salle Hotel, Chicago. The speaker for the dinner at noon, when the society will launch a campaign for children's services, will be Dr. Henry H. Work, New York, and his subject, "Mental Hygiene Needs of Children—1948."

Physical Therapists Meeting.—The Illinois Chapter of the American Physical Therapy Association will hold its regular monthly meeting on March 3 at 7.30 p.m. at Martin's Lounge, 120 South La Salle Street, Chicago. Dr. Fred P. Robbins, Michael Reese Hospital, will conclude a series of three lectures on "Psychosomatic Medicine." Dinner will be served at 6.30 p.m.

Townships Quarantined for Rabies.—A campaign to eliminate a rabies menace, which has already resulted in quarantine in Bloom, Worth, Thornton and Rich townships in Cook County, is being planned by the county health department. The number of cases in the quarantine sections is the highest in seven years, according to Dr. Edward A. Piszczek, county health director. Both Bremen townships and parts of Calumet township are on the borderline of emergency classification. One objective will be to clean up the stray dog situation.

Meeting on Diseases of the Heart.—A joint meeting of the Illinois Heart Association and the Sangamon County Medical Society will be held March 4 at the Memorial Hospital, Springfield, beginning at 2 p.m. After clinicopathologic demonstrations, Dr. Thomas H. Burford, St. Louis, will speak on "Surgery of Congenital Cardiovascular Defects" and Dr. Don C. Sutton, Chicago, "Prognosis in Heart Disease." A panel discussion will begin at 4.30 p.m. At the evening meeting at the Elks Club, Dr. Harry A. Durkin, Peoria, will speak on "American Heart Associations" and Dr. Arlie R. Barnes, Rochester, Minn., on "The Treatment of Congestive Heart Failure."

Chicago

Projector for Educational Film.—A movie projector, gift of the Illinois Women's Golf Association, has been installed in the Museum of Science and Industry for showing films on cancer. The projector automatically shows an educational film dealing with the cell origin, danger signals and necessity for early treatment of cancer.

The Twenty-Fourth Hektoen Lecture.—The twenty-fourth Ludvig Hektoen Lecture of the Frank Billings Foundation will be delivered at the Palmer House on Friday evening, March 26, at 8 o'clock by Dr. Percival Bailey, professor of neurology and neurologic surgery, University of Illinois College of Medicine, on "Organization of the Cerebral Cortex."

Special Society Meeting.—Members of the Chicago Laryngological and Otological Society will be guests of the staff of Illinois Eye and Ear Infirmary at a dinner at 6 p.m., March 1. Richard Silverman, administrative director, Central Institute for the Deaf, St. Louis, will speak on "What is Audiology?" A panel discussion on speech and hearing rehabilitation will also be held.

Dr. Colowick Appointed Associate Professor.—Sidney P. Colowick, Ph.D., an associate in the division of nutrition and physiology at the Public Health Research Institute, New York, has been appointed associate professor of biologic chemistry at the University of Illinois College of Medicine, effective April 1. Dr. Colowick is a graduate of Washington University at St. Louis. During the war he conducted civilian research on chemical warfare agents under contract with the Office of Scientific Research and Development. Dr. Colowick received the Eli Lilly award in biologic chemistry in 1947.

Dr. Ballenger Appointed Director of Department.—Dr. Howard C. Ballenger, who has been a member of the faculty since 1930, has been appointed professor of otolaryngology and chairman of the department in Northwestern University Medical School, succeeding Dr. John Gordon Wilson, retired. Dr. Ballenger received his doctor's degree in medicine from the University of Indiana, 1911. Formerly a consultant to the United States Public Health Service, he is past president of the Chicago Laryngological and Otological Society.

MAINE

Course in Basic Ophthalmology.—The Ophthalmological Study Council, Boston, will offer a course on the basic subjects of ophthalmology at Westbrook Junior College, Portland, June 19 to September 11. The course has proved its value in enabling students to secure residencies and in preparation for examinations of the American Board of Ophthalmology. The course comprises laboratory work in pathology, optics, refraction and slit lamp. Last summer the student enrolment was one hundred and twenty; it will be cut this year to one hundred.

MISSOURI

Meeting of Anesthesiologists.—The regional meeting of the American Society of Anesthesiology and the Kansas City Society of Anesthesiology will be held at the Hotel President, Kansas City, April 4-6. Clinics will be held Monday morning at Research and St. Joseph hospitals in Kansas City, Mo., and at Providence Hospital and the University of Kansas Medical Center, Kansas City, Kan. There will be a symposium on intravenous procaine Tuesday morning, another on spinal, regional and therapeutic nerve block and a third on curare and curare-like compounds in the afternoon.

NEW JERSEY

Dr. English Retires.—Dr. Samuel B. English, superintendent and medical director of the state sanatorium at Glen Gardner since it was established forty years ago, retired Nov. 1, 1947. He is said to be the second oldest superintendent of a tuberculosis hospital in point of service in the United States. The Samuel B. English Memorial Library was dedicated at the sanatorium two years ago. Dr. Joseph A. Smith, assistant medical director, succeeds Dr. English.

Study of Hormones.—A $3,600 grant from the Research Corporation, a nonprofit organization, for research on hormones has been received by Rutgers University, New Brunswick, to support the work of Roderick A. Barnes, Ph.D., assistant professor of chemistry. The Rutgers project involves a study of general methods for the synthesis of steroid compounds, a general classification of naturally-occurring compounds such as the male and female sex hormones, the hormones of the adrenal cortex and bile acids. Dr. Barnes joined the faculty at Rutgers last fall after teaching for two years at Columbia University, New York. He completed his graduate work at the University of Minnesota, Minneapolis, in 1943.

NEW YORK

Niagara Falls Clinical Day.—The Niagara Falls Academy of Medicine will hold its annual Clinical Day March 6 at the Hotel Niagara. Dr. George Crile, Cleveland, will speak on "The Present Status of Propylthiouracil and of Surgery in the Treatment of Hyperthyroidism"; Dr. Foster Kennedy, New York, "The Allergic Influence in Migraine," and Dr. William Bates, Philadelphia, "Simulation of Thoracic and Abdominal Visceral Pathology by Segmental Neuralgia." At the banquet at 7 p m. Dr. Maurice Chideckel, Baltimore, will speak on "The General Practitioner."

Six Regional Health Officers Appointed.—Regional Health Officers to head the six newly established state health regions have been appointed by the state health department. They are Drs. Archibald S. Dean, Buffalo; Joseph P. Garens, Rochester; Ray D. Champlin, Oneonta; Ralph M. Vincent, Binghamton; Robert L. Vought, Rochester, and Philip J. Rafle, Forest Hills. The appointments are effective March 16, and regional offices will be opened as soon thereafter as possible. The appointments are based on recent civil service promotion examinations. The salary range is $7,000 to $8,500. Offices of the five upstate health regions will be located at Buffalo, Rochester, Syracuse, Albany and New York City. The sixth region, which will serve New York City only, will also have offices there.

Postgraduate Instruction in Richmond County.—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged postgraduate instruction for the Richmond County Medical Society to be given Friday afternoons at 4.30 in the auditorium of the U. S. Marine Hospital, Stapleton, Staten Island.

March 5: Dr. Harry Gold, New York, The Management of the Failing Heart.

March 12: Dr. Albert F. R. Andresen, New York, Gastrointestinal Hemorrhage.

March 19: Dr. David Goldblatt, New York, Treatment of Burns and Hand Infections.

March 26: Dr. George T. Pack, New York, Cancer of the Stomach.

On March 18 the Geneva Academy of Medicine will hear Dr. Joseph E. J. King, New York, speak on "Head Injuries and Brain Abscess" at the Seneca Hotel, Geneva, 8:30 p. m. Dr. Ferdinand J. Schoeneck, Syracuse, will speak on "Gynecology in General Practice" before the Tompkins County Medical Society Monday, March 15, at 8:30 p. m., at the Tompkins County Memorial Hospital, Ithaca.

New York City

Dr. Steele Appointed Professor.—Dr. J. Murray Steele, associate professor of medicine at New York University College of Medicine since 1939, has been appointed a full professor of medicine and remains director of the Third Research Service, Goldwater Memorial Hospital. For a year and a half Dr. Steele has been director of the New York University Medical Division of Lenox Hill Hospital, and he has recently undertaken research at Goldwater Memorial Hospital in connection with disease associated with old age. He is a graduate of Johns Hopkins Medical School, Baltimore, has been an instructor at the University of Chicago School of Medicine and from 1929 to 1939 was an assistant, then an associate in medicine, at the hospital of the Rockefeller Institute for Medical Research.

Graduate Course in Industrial Medicine.—The Long Island College of Medicine will present its fifth graduate course in industrial medicine April 5-16, under the auspices of the department of preventive medicine and community health. The objective of the course is to provide physicians engaged in full time or part time industrial practice an opportunity to become acquainted with recent developments in industrial medicine. The course will be of special interest also to industrial nurses, hygienists and engineers, personnel workers, representatives of management and labor, and other groups concerned with the health of employees. Tuition for the course will be $75. Inquiries should be addressed to Dr. Thomas D. Dublin, Department of Preventive Medicine and Community Health, 248 Baltic Street, Brooklyn 2.

Lectures for Family Doctors.—A community project to aid family doctors in keeping abreast of medical developments will be inaugurated March 1 at the New York University College of Medicine. Heart disease, psychiatry, anesthesia, dermatology, rehabilitation and physical medicine will be treated in twenty-four clinical sessions; these will be open, free of charge, to members of the medical profession, with faculty members of the college of medicine in charge. Plans call for the clinics to be conducted throughout March, April and May. Registration must be made in advance. Although alumni of the college of medicine are being given preference, effort is being made to accommodate other physicians, and they may obtain information by writing the alumni office at the college, 477 First Avenue, New York 16. All clinics will occur from 4 to 6 o'clock in the afternoon or from 8 to 10 o'clock at night. Half of the two hour sessions will be used for presentation of subject matter, using patients in clinical procedure, and the second hour for open forum discussion. Each special area of medicine will be comprehensively presented over a period of four or six weeks.

NORTH CAROLINA

Memorial Fellowship.—The Charles Hartwell Cocke Memorial Fellowship has been established with the National Tuberculosis Association by a gift of $5,000 from Mrs Charles Hartwell Cocke of Asheville, N. C., in memory of her late husband. Dr. Cocke was a former member of the association.

PENNSYLVANIA

Secretaries and Editors Conference.—The thirty-sixth annual Secretaries and Editors Conference will be held in Harrisburg, Thursday afternoon and evening, March 18, and Friday morning March 19. Officers of the state society, chairmen of the committees on public health legislation, public relations and medical economics are invited to attend, along with county society secretaries and editors of county society bulletins. Representatives of other societies, including the American Medical Association, will be guests. The program will be made up of discussions and round tables. County societies are urged to send their representatives.

Philadelphia

Award for Allergy Paper.—The Philadelphia Allergy Society has established the annual Lillian Snyder Award of $50 for its members, to be presented for the most outstanding paper read at the annual meeting of the society. The award is made possible by a gift from Mr. Louis Snyder in appreciation of the services rendered by a Philadelphia allergist.

Graduate Course in Chest Diseases.—The American College of Chest Physicians, the Pennsylvania Chapter and the Laennec Society of Philadelphia will sponsor the first annual Postgraduate Course in Diseases of the Chest at the Warwick Hotel, Philadelphia, March 15-20. The course will be limited to fifty physicians, applications being accepted in the order received at the American College of Chest Physicians, 500 North Dearborn Street, Chicago 10. The fee of $50 should be enclosed with the application.

Atomic Energy Steering Committee.—The Hospital Council of Philadelphia and the Red Cross, together with members of the medical profession, have formed the Atomic Energy Medical Steering Committee to educate physicians, nurses, hospital personnel and the public in the medical aspects of atomic energy and how to care for and prevent injuries from radioactive substances. Methods include monthly lectures, the first of which drew 250 persons to hear Col. James P. Cooney, M.D., in a talk sponsored jointly with the 248th Medical Unit, M.R.C. Dr. Theodore R. Fetter, president of the Philadelphia County Medical Society, is chairman of the committee.

Pittsburgh

Dr. Rawson to Give Memorial Lecture.—The Doctors Charles and Karl Emmerling Memorial Lecture will be given Tuesday, March 9, 1948, in the rooms of the Academy of Medicine, 322 North Craig Street, by Dr. Rulon W. Rawson, Boston, on "The Effect of Therapeutic Agents on the Pathologic Physiology of Graves' Disease."

Premedical Chapter Installed.—Chi Rho Nu, premedical fraternity of the University of Pittsburgh, became the fortieth chapter of Alpha Epsilon Delta, national honorary premedical fraternity, on its installation as the Pennsylvania Gamma Chapter on January 17. The initiation of one hundred and fifteen active and ten honorary members was conducted by national officers of the fraternity.

TEXAS

Phi Beta Pi Lecture.—Dr. Charles H. Best, University of Toronto, Canada, will deliver the annual Phi Beta Pi lecture at Baylor University College of Medicine, Houston, on the evening of March 22, and will spend the remainder of that week as a visiting professor in the department of physiology.

Society Election.—The Texas Society of Pathologists, at its annual meeting in Galveston, January 25, elected Dr. William W. Coulter, Houston, president; Dr. John F. Pilcher, Corpus Christi, president-elect; Dr. Charles T. Ashworth, Dallas, secretary. Dr. Theodore J. Curphey, Garden City, N. Y., was guest of the society.

WEST VIRGINIA

Health Officers to Teach at State Schools.—Two county health officers recently confirmed by the public health council will teach classes in public health at state schools in addition to performing their official duties. Dr. Milton I. Roemer, Washington, D. C., who became health officer for Monongalia County February 1, will teach public health at West Virginia University, Morgantown Dr. Alford G. Evans, Washington, D. C., who assumed his duties as health officer for Marion County February 1, will teach at Fairmont State Teachers College. Both officers have a master's degree in public health.

Survey of Practicing Physicians.—The state health department, as the result of an order entered at the last meeting of the public health council, is undertaking a survey of physicians practicing in West Virginia. The state has no law requiring the annual or biennial registration of physicians. The state health commissioner has mailed a questionnaire to every physician in the state asking for statistical information. This questionnaire should be filled out and returned without delay. Additional copies may be obtained from the state health department, local medical societies and the West Virginia State Medical Association.

Premature Nursery Established.—The premature nursery, established at the Herbert J. Thomas Memorial Hospital in South Charleston, sponsored by the state department of health, was opened February 16. Incubators furnished by the division of maternal and child health have been placed in the pediatric ward of the hospital. The nursery is a demonstration center; if it proves successful, other premature nurseries will be established throughout the state in an effort to reduce the mortality of premature infants in West Virginia. The new nursery will be used as a training center in this type of work. Preference will be given graduate nurses until space and personnel permit the training of a larger group. The nursery is in charge of Miss Mary Alice Sinclair, who has received special training in Chicago for this work under the auspices of the state health department.

WISCONSIN

Personal.—Dr. Walter J. Urben, Madison, director of the Wisconsin State Public Welfare Department's mental hygiene division since 1942, has been appointed superintendent of the Mendota State Mental Hospital, Mendota.

Anniversary of Occupational Therapy Department.—Milwaukee-Downer College will observe the thirtieth anniversary of its department of occupational therapy March 23. Dr. Howard A. Rusk, chairman, department of rehabilitation and physical medicine, New York University College of Medicine, will present "Today's Challenge to Occupational Therapy." The department of occupational therapy was set up at Milwaukee-Downer in 1918 by Mrs. Carl H. Davis, now of Wilmington, Del., in response to the call of Gen. John J. Pershing for a thousand women volunteers to do bedside occupational work. When in 1918 the term "occupational therapy" was first used, a new profession was born. Marjorie Taylor, director of the department at Milwaukee-Downer from 1929 to 1939, developed the studies into a course leading to a B.S. degree. Miss McNary, who has directed the department since 1939, also conducted courses for the Army during World War II.

GENERAL

Course for Medical Record Librarians.—The American Association of Medical Record Librarians this year will give extension courses throughout the country. Three types of courses are being offered: a two week basic course for beginners, the one week regular course as previously given, and an advanced course, or workshop. Any one working in the medical record department of a hospital is eligible to attend any course unless definite prerequisites are stated. The following programs are scheduled: March 29-April 2, the regular course at Tulsa, Okla.; April 5-16, a two week beginners' course at Houston, Texas; May 23-28, an advanced course at Denver. For information address Edna K. Huffman, R.R.L., American Association of Medical Record Librarians, 18 East Division Street, Chicago.

A Million for Poliomyelitis Research.—The National Foundation for Infantile Paralysis reports as of February new grants and appropriations totaling $1,188,785.40 for research and education in hospitals and other institutions in the United States and Canada. Of the new appropriation, $350,000 is to continue the foundation's physical therapy program, $200,000 for fellowships in professional education and $35,000 for new scientific exhibits. The George William Hooper Foundation, University of California Medical School, Berkeley-San Francisco, was granted $43,090 to continue its study of poliomyelitis epidemics, diagnostic procedures, transmission of the disease and possible reservoirs of the virus. The University of Pennsylvania, Philadelphia, received $136,500 for a five year study to evaluate treatment methods to ameliorate the crippling after-effects of poliomyelitis; Children's Hospital, Philadelphia, $25,000 to continue studies on the effect of dietary factors and nutrition on resistance to poliomyelitis; University of Southern California, Los Angeles, $28,800 to continue studies of types of virus which can cause the disease, and $13,400 for a study of the growth requirements of the virus; Emory University, Atlanta, received $22,880 to develop better methods for diagnosis and $11,300 for a study of differences in muscle cells in relation to susceptibility to paralysis.

Southwest Allergy Forum.—The 1948 meeting of the Southwest Allergy Forum will be held April 5-6, at the Biltmore Hotel, Oklahoma City, under the presidency of Dr. Herbert J. Rinkel of Kansas City, Mo. The program for Monday includes a roundtable discussion on seasonal hayfever. Guest speakers will be Dr. Bernardine T. McMahon, Denver, on "Bronchiectasis" and Dr. Jonathan Forman, Columbus, on "Urticaria." On Tuesday there will be a roundtable discussion on asthma and a talk by Dr. Karl D. Figley, Toledo, president of the American Academy of Allergy.

Dr. Diamond Appointed Technical Director of Blood Program.—Dr. Louis K. Diamond, assistant professor of pediatrics, Harvard Medical School, Boston, was appointed on February 2 technical director of the national blood bank program of the American Red Cross. Dr. Diamond, who has been associated with Harvard Medical School since his graduation in 1927, directed the first large scale blood laboratory, which was established at Children's Hospital, Boston, in 1942.

Elmer Hess Prize in Urology.—The Western New York and Ontario Urological Society announces the annual Elmer Hess Prize, which includes $25 plus the winner's own personal hotel expense while attending the meeting at which the paper will be read. Eligible are residents or interns in urology, or urologists with not more than two years in practice who reside in the society's area. The paper may be on any subject related to urology and shall be limited to ten triplespaced pages. Three copies of the paper should be mailed to Dr N. W. Roome, 170 St. George Street, Toronto 5, Ontario, Canada, before June 1, 1948.

Industrial Physicians and Surgeons Meeting.—The American Association of Industrial Physicians and Surgeons will hold its thirty-third annual meeting at the Hotel Statler, Boston, March 30 to April 2, under the presidency of Dr. Henry S. Brown, Detroit. The program will begin Tuesday morning with a clinic at the Massachusetts General Hospital. Joseph C. Aub, Boston, will speak on "Recent Studies in Beryllium" and Edwin F. Cave and Charles B. Burbank, Boston, on "The Surgery of Trauma." Other speakers include:

TUESDAY

Joseph H. Shortell, Boston, Shoulder Injuries.
William F. Flynn, Boston, Infections of the Hand.
Albert A. Hornor, Boston, Industrial Problem in Diabetes Mellitus.
John D. Adams, Boston, Double Plating of Long Bones, End Results.

WEDNESDAY

Edward E. F. Adolph, Ph.D., Rochester, N. Y., Theodore F. Hatch, Pittsburgh, and Arlie Bock, Boston, Papers on the Subject of Heat.
James M. Dunning, Boston, Public Health Aspect of Dentistry in Industry.
Selden D. Bacon, Ph.D., New Haven, Conn., Alcoholism in Industry.
Oliver Cope and Francis D. Moore, Boston, Management of Burns.
Arthur L. Watkins, Boston, and George G. Deaver, New York, Seminar in Physical Medicine.

THURSDAY

George E. Morris, Boston, The Skin: the Fragile Element in Industrial Production.
Chester S Keefer, Boston, Chemotherapy and Antibiotics.
Howard B Sprague, Boston, Coronary and Other Heart Disease.
Chester M. Jones, Boston, Management of Peptic Ulcer.
Hugh F. Hare, G. Edmund Haggart and James L. Poppen, Boston, Seminar on Back Pain.

The annual banquet will be April 1 at 7 p.m. Dr. Frank H. Lahey, director of the Lahey Clinic, Boston, will speak on "Problems and Advances in Medicine and Surgery."

CORRECTION

Dosage of Antimonium Potassium Tartrate.—The last sentence in the letter to the Editor entitled Schistosomiasis by F. Gordon Cawston, Durban, South Africa, in The Journal, Dec. 27, 1947, page 1167, should read: "An injection of 0.1 Gm. may well be regarded as the maximum."

Deaths

Benjamin Franklin Gallant ✠ Northport, N. Y.; born in Somerville, Mass., March 25, 1879; College of Physicians and Surgeons, Baltimore, 1913; formerly associated with the Gouverneur Hospital, Bellevue and Allied Hospitals and the Lying-In Hospital in New York, Kankakee (Ill.) State Hospital, Lincoln (Ill.) State Hospital, St. Vincent's Hospital in Bridgeport, Conn., and the Mather Memorial Hospital in Port Jefferson; served as resident director of the Charity Hospital and medical director of St. Luke's Private Sanitarium in New Orleans; at one time owner and director of the Belvidere Private Sanitarium in New Orleans and medical director of Dr. Gallant's Neurological Hospital in Pass Christian, Miss.; died Nov. 10, 1947, aged 68, of coronary thrombosis.

Curtis Field Burnam ✠ Baltimore; born Jan. 17, 1877; Johns Hopkins University School of Medicine, Baltimore, 1900; associate professor of surgery at his alma mater; member of the House of Delegates of the American Medical Association in 1915; member of the American Gynecological Society, Southern Surgical Association and the American Radium Society; fellow of the American College of Surgeons; in 1936 received the Janeway Medal from the American Radium Society; co-author with Dr. Howard A. Kelly of "Diseases of the Kidneys, Ureters and Bladder" ; affiliated with the Church Home and Infirmary, Hospital for the Women of Maryland, Johns Hopkins Hospital and the Union Memorial Hospital, where he died Nov. 29, 1947, aged 70, of pneumonia.

J. Ross Hunter ✠ Charleston, W. Va.; born in New Sterling, N. C.; Feb. 26, 1880; Medical College of Virginia, Richmond, 1903; fellow of the American College of Surgeons; member of the board of directors of the American Cancer Society; member of the board of directors and the executive committee of the West Virginia Cancer Society, which he helped to organize; served during World War I; at one time chief of the surgical staff of the Sheltering Arms Hospital at Hansford; one of the organizers, a trustee and for many years superintendent of the Mountain State Memorial Hospital; president of the staff of the Herbert J. Thomas Memorial Hospital in South Charleston; died Dec. 31, 1947, aged 67, of coronary thrombosis.

Hiram Edgar Miller ✠ San Francisco; born in Dixon, Ill., Aug. 30, 1891; University of California Medical School, San Francisco, 1917; clinical professor and chairman of the department of dermatology at his alma mater; specialist certified by the American Board of Dermatology and Syphilology; member of the American Dermatological Association and the American Academy of Dermatology and Syphilology; served in France during World War I; affiliated with the San Francisco, Southern Pacific General, St. Luke's, Mount Zion and Children's hospitals; died in the University of California Hospital recently, aged 56.

Richard Covert Satterlee ✠ Captain, M.C., U. S. Navy, retired, San Francisco; born in Layfayette, Ind., Jan. 13, 1894; George Washington University School of Medicine, Washington, D. C., 1917; specialist certified by the American Board of Pathology, Inc.; entered the medical corps of the U. S. Navy in September 1917; served during World Wars I and II; retired for disability in line of duty; served as executive officer at the U. S. Naval Convalescent Hospital in Yosemite National Park, Calif.; died in the United States Naval Hospital in Mare Island, Calif., May 16, 1947, aged 53, of hypertension.

Benjamin Franklin Hambleton, Houston, Texas; born in 1872; University of Wooster Medical Department, Cleveland, 1900; professor of physiology and pharmacology at Baylor University College of Medicine; formerly professor of physiology and pharmacology at the Vanderbilt University School of Medicine in Nashville, Tenn., where he also served as acting dean and secretary of the medical school; at one time professor of physiology at the Cleveland College of Physicians and Surgeons, Medical Department, Ohio Wesleyan University; died Dec. 9, 1947, aged 75, of coronary occlusion.

Donald Carl Snyder ✠ Colonel, U. S. Army, retired, Longmont, Colo.; born in Belle Plaine, Iowa, March 17, 1896; State University of Iowa College of Medicine, Iowa City, 1919; Army Medical School and Medical Field Service School in 1929; served during World War I; entered the medical corps of the U. S. Army as a first lieutenant in 1927; a lieutenant colonel and colonel during World War II; retired for disability in line of duty on May 31, 1945 with rank of colonel; died in Fitzsimons General Hospital, Denver, Dec. 21, 1947, aged 51, of mitral stenosis and bronchial asthma.

Harry Garrett Miller, Millville, N. J.; born Sept. 11, 1869; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the American Medical Association; past president and for many years secretary of the Cumberland County Medical Society; county physician; past president of the city council; member of the U. S. Pension Board for many years; active on the Selective Service Board during World War II; on the staff of the Millville Hospital since its inception, serving as president for four terms; died Nov. 30, 1947, aged 78, of coronary thrombosis.

Archibald John Alcorn, Chicago; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1900; died recently, aged 80.

Ella Mary Anderson, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1893; died in the Woman's Hospital recently, aged 83, of pulmonary edema.

Pasquale Assante, Philadelphia; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1891; died in the Jefferson Hospital Nov. 22, 1947, aged 82, of arteriosclerosis.

William Simpson Bailey, Poplar Bluff, Mo.; St. Louis College of Physicians and Surgeons, 1898; formerly member of the school board; served as registrar of vital statistics in Butler County; died Nov. 27, 1947, aged 81, of myocarditis.

Howard Roswell Bankerd, Port Townsend, Wash.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; died recently, aged 72, of heart disease.

John Albert Bennett, Elmira, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1905; member of the American Medical Association; died Nov. 21, 1947, aged 67, of cerebral thrombosis and bronchopneumonia.

William Clement Bosley, Houston, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1900; died Nov. 22, 1947, aged 72.

George Cummings Bower ✠ Marcy, N. Y.; University of Buffalo School of Medicine, 1922; specialist certified by the American Board of Pathology, Inc.; fellow of the American College of Physicians; member of the American Society of Clinical Pathologists; associate editor of the Psychiatric Quarterly; director of clinical laboratories at the Marcy State Hospital, where he died Dec. 1, 1947, aged 46.

Melville Grant Boyd, Dalton, Mass.; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1929; member of the American Medical Association; served during World War II; died recently, aged 49, in Kingston, Ontario.

Joseph Holmes Branson ✠ Washington, D. C.; Southern Homeopathic Medical College, Baltimore, 1894; died Nov. 30, 1947, aged 81, of cerebral embolus.

John Q. Brantley, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1905; affiliated with the Crawford W. Long Hospital, where he died Nov. 21, 1947, aged 66, of arteriosclerosis and pneumonia.

Norman Christopher Browand, Hermosa Beach, Calif.; Fort Wayne (Ind.) College of Medicine, 1896; formerly on the staff of the Miami Valley Hospital in Dayton, Ohio; died in Glendale, Calif., Nov. 30, 1947, aged 81, of cerebral hemorrhage.

Edwin Rutherford Butterfield ✠ Burbank, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; died Nov. 29, 1947, aged 63.

James Frank Cadenhead, Weinert, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1914; member of the American Medical Association; for many years president of the school board; served during World War I, and during World War II chairman of the medical division of the selective service board of Haskell County; died Nov. 21, 1947, aged 56, of carcinoma.

Howard Allen Calvert, Frederick, Okla.; John A. Creighton Medical College, Omaha, 1912; member of the American Medical Association; served during World War I; affiliated with the Frederick Clinic Hospital and the Spurgeon, Arrington and Allen Hospital and Clinic; died Nov. 27, 1947, aged 58, of coronary thrombosis.

William Rogers Castle, Paintsville, Ky.; Hospital College of Medicine, Louisville, 1907; member of the American Medical Association; served as a member of the city council; died Nov. 29, 1947, aged 65, of diabetes mellitus.

Timothy L. Chiasson, ✠ Neponset, Ill.; Loyola University School of Medicine, Chicago, 1916; an examining physician for the county selective service board during World War II; member of the local board of health; affiliated with the Public Hospital and St. Francis Hospital in Kewanee; died Dec. 6, 1947, aged 60, of coronary heart disease.

Floyd Clardy ⊕ Hot Springs National Park, Ark.; University of Tennessee College of Medicine, Memphis, 1916; served during World War I; affiliated with the Methodist Hospital and St. Joseph's Infirmary; died Nov. 22, 1947, aged 59, of hypertension and cerebral hemorrhage.

Eliza Cook, Gardnerville, Nev.; Cooper Medical College, San Francisco, 1884; died recently, aged 91.

Thomas Joseph Coyne ⊕ Boston; Tufts College Medical School, Boston, 1901; affiliated with Children's, St. Elizabeth, St. Margaret's and Harley hospitals; died Dec. 4, 1947, aged 75, of heart disease.

William Henry Crawford, Jackson, Miss.; John A. Creighton Medical College, Omaha, 1914; served during World Wars I and II; affiliated with the Veterans Administration Hospital; died Nov. 25, aged 58, of postoperative shock.

Whitfield Walker Crook ⊕ Cuthbert, Ga.; University of the South Medical Department, Sewanee, Tenn., 1908; served during the Spanish-American War and World War I; died Nov. 11, 1947, aged 67, of heart disease and pulmonary embolism.

James Erric Cudd ⊕ Spartanburg, S. C.; University of Maryland School of Medicine, Baltimore, 1916; for many years county physician; died in Mary Black Memorial Hospital Nov. 14, 1947, aged 56, of acute pancreatitis.

Hyman Dickman, Philadelphia; Maryland Medical College, Baltimore, 1911; died recently, aged 64, of cerebral thrombosis and diabetes mellitus.

Gustave William Dishong ⊕ Omaha; born in San Francisco, Nov. 9, 1874; John A. Creighton Medical College, Omaha, 1907; for many years professor and head of the department of nervous and mental diseases at his alma mater, where in 1939 he retired with the title of professor emeritus; fellow of the American College of Physicians; member of the American Psychopathological Association; served in France during World War I; affiliated with St. Joseph's Hospital, where he died Nov. 24, 1947, aged 73, of carcinoma of the rectum.

Henry Aaron Dittmer, Manchester, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1884; died Nov. 26, 1947, aged 89, of senility.

Libby Russell Doll, St. Louis; American Medical College, St. Louis, 1901; died Nov. 9, 1917, aged 75, of heart disease.

Walter Livingston Dunning ⊕ Paterson, N. J.; Long Island College Hospital, Brooklyn, 1898; died Nov. 29, 1947, aged 71, of myocardial infarction and arteriosclerosis.

Mark Matthew Duffy, Chicago; Bennett Medical College, Chicago, 1915; received the Distinguished Service Cross for bravery in France during World War I; died Dec. 11, 1947, aged 57, of acute cardiac dilatation.

Sarah May Edwards, Bloomfield, N. J.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1899; died in the Community Hospital, Montclair, Nov. 23, 1947, aged 78, of cerebral hemorrhage and hypertension.

William G. Estill, Lawson, Mo.; Missouri Medical College, St. Louis, 1883; died Nov. 27, 1947, aged 87, of cardiorenal disease.

Joseph Otto Evans, Linden, N. J.; Johann Wolfgang Goethe-Universität Medizinische Fakultät, Frankfurt-am-Main, Prussia, Germany, 1922; member of the American Medical Association; school physician; physician for the child health clinic of the board of health; died Nov. 23, 1947, aged 49, of myelogenous leukemia.

William Rollie Ferster, Kansas City, Mo.; University Medical College of Kansas City, Mo., 1908; member of the American Medical Association; died Nov. 11, 1947, aged 74, of cerebral hemorrhage, hypertension and hypertrophic arthritis.

Simon Sylvester Foster, Atlanta, Ga.; University of Tennessee College of Medicine, Memphis, 1911; at one time company physician for the Stearns Coal and Lumber Company in Stearns, Ky.; for many years on the staff of the Veterans Administration Hospital; died Nov. 27, 1947, aged 60, of coronary occlusion.

Claude Augustine Frink ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1902; fellow of the American College of Surgeons; formerly a lieutenant in the U. S. Naval Reserve; surgeon at the Knickerbocker Hospital; died recently, aged 71, of heart disease.

James De Witt George, Los Angeles; Indiana University School of Medicine, Indianapolis, 1926; member of the American Medical Association; served on the staff of the Compton (Calif.) Sanitarium and as chief resident physician at the William H. Coleman Hospital for Women, Indianapolis; died Nov. 16, 1947, aged 48.

Thomas M. Glasgow ⊕ Passaic, N. J.; Baltimore Medical College, 1902; on the staff of the Passaic General Hospital; died Nov. 29, 1947, aged 69, of coronary thrombosis.

Marvin Myers Gould ⊕ Surgeon, Lieutenant Commander, U. S. Navy, retired, Boston; entered the U. S. Navy in June 1919; retired June 30, 1939; served during World War II; on Jan. 24, 1943 the Navy Department announced the award of a letter of commendation for his services in caring for victims of the Cocoanut Grove fire in Boston on Nov. 28, 1942; died at Barranquilla, Colombia, Nov. 14, 1947, aged 57.

Moritz Gross ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1898; affiliated with the Park West Hospital; died in the Beth David Hospital recently, aged 74.

Gordon Milton Grundy ⊕ Newport Beach, Calif.; McGill University Faculty of Medicine, Montreal, Canada, 1913; served during World War I; died in St. Joseph Hospital, Orange, Calif., Dec. 16, 1947, aged 61, of cerebral hemorrhage.

Charles Nicholas Harper ⊕ New York; University of Virginia Department of Medicine, Charlottesville, 1915; specialist certified by the American Board of Otolaryngology; affiliated with the Roosevelt Hospital; died Nov. 26, 1947, aged 57, of heart disease.

John Calvin Hartman ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1917; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; served during World War I; affiliated with the Abington (Pa.) Memorial Hospital and Germantown Hospital; died Dec. 13, 1947, aged 56, of coronary thrombosis.

Charles Cheves Haskell ⊕ Richmond, Va.; Harvard Medical School, Boston, 1908; at one time professor of physiology and pharmacology at the Medical College of Virginia; president of the Charles C. Haskell Company; affiliated with the Johnston-Willis Hospital; died Nov. 12, 1947, aged 67, of cerebral hemorrhage.

Selmar Frederick Hauser, Covington, Ky.; University of Cincinnati College of Medicine, 1916; served in France during World War I; member of the American Medical Association; died in St. Elizabeth Hospital Nov. 26, 1947, aged 54.

Thomas Southall Hawkins, Baltimore; Howard University College of Medicine, Washington, D. C., 1900; died recently, aged 77, of carcinoma of the prostate.

Frederick Edward Hesser, Baltimore; Southern Homeopathic Medical College, Baltimore, 1904; served on the staff of the Church Home and Infirmary; died in Shamokin, Pa., Nov. 24, 1947, aged 72, of cerebral thrombosis and bronchopneumonia.

George H. Hocking ⊕ Baltimore; University of Maryland School of Medicine, 1879; an Affiliate Fellow of the American Medical Association; died Nov. 25, 1947, aged 92, of arteriosclerosis and pneumonia.

Benjamin F. Humphrey, Sturgis, Ky.; University of Louisville (Ky.) Medical Department, 1901; past president of the school board; died Nov. 25, 1947, aged 70, of coronary thrombosis.

Walter Eugene Hurley ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1908; also a graduate in pharmacy; examiner for the local draft board during World War I; for many years affiliated with St. Catherine's and St. Mary's hospitals; died in the Mercy Hospital, Rockville Centre, Dec. 14, 1947, aged 66, of carcinoma of the rectum.

Herman Samuel Jacobs, New York; University and Bellevue Hospital Medical College, New York, 1908; died Nov. 10, 1947, aged 61.

Carl Emanuel Johnson, Pine River, Minn.; Rush Medical College, Chicago, 1903; member of the American Medical Association; died in Fort Dodge, Iowa, Nov. 11, 1947, aged 74, of arteriosclerosis and paralysis agitans.

John Francis Kelly, Scranton, Pa.; Cornell University Medical College, New York, 1910; member of the American Medical Association; affiliated with the Mercy Hospital, St. Mary's Hospital and the Scranton State Hospital, where he died Nov. 30, 1947, aged 64, of uremia.

Richard James Kelly ⊕ New York; University of Pennsylvania School of Medicine, Philadelphia, 1928; specialist certified by the American Board of Dermatology; member of the American Academy of Dermatology and Syphilology; affiliated with the Vanderbilt Clinic and Roosevelt Hospital; died Nov. 27, 1947, aged 45, of a skull fracture.

Peter Ernest Kierland ⊕ Alexandria, Minn.; Rush Medical College, Chicago, 1902; died Nov. 26, 1947, aged 69, of coronary thrombosis.

Charles Kleiman ⊕ Orangeburg, N. Y.; Tufts College Medical School, Boston, 1931; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; associate in neurology and psychiatry at the Long Island College of Medicine in Brooklyn; affiliated with the Rockland State Hospital; died Nov. 20, 1947, aged 42, of coronary thrombosis.

Mary Jeannette Lower, Kansas City, Mo.; Southwest School of Medicine and Hospital, Kansas City, 1916; member of the American Medical Association; died in Burlington, Iowa, Nov. 27, 1947, aged 80.

Robert Price McClellan ⊕ Irwin, Pa.; Jefferson Medical College of Philadelphia, 1888; chairman of the board of directors and past president of the First National Bank; died in the Westmoreland Hospital in Greensburg, recently, aged 84, of injuries received in an automobile accident.

Ward Benefiel McMakin, Camas, Wash.; Eclectic Medical Institute, Cincinnati, 1903; member of the American Medical Association; died recently, aged 71.

John Bowdoin Mears ⊕ Medical Director, Captain, U. S. Navy, retired, Keller, Va.; University of Virginia Department of Medicine, Charlottesville, 1901; entered the U. S. Navy in 1905 and retired Sept. 1, 1936 for incapacity resulting from an incident of the service; died Nov. 16, 1947, aged 68.

Hugh William Mullins, Helena, Mont.; Loyola University School of Medicine, Chicago, 1919; formerly affiliated with Alexian Brothers' and St. Mary of Nazareth hospitals in Chicago; died in St. John's Hospital Dec. 7, 1947, aged 61, of intestinal carcinoma.

Joseph Berchmain O'Neill, Pawtucket, R. I.; University of Maryland School of Medicine, Baltimore, 1900; died recently, aged 76.

John Randolph Quinn Jr., New York; Cornell University Medical College, New York, 1913; died in St. Luke's Hospital recently, aged 60.

Arthur T. Revell, Columbus, Kan.; Kansas City (Mo.) Medical College, 1900; member of the American Medical Association; affiliated with Mount Carmel Hospital in Pittsburg, where he died recently, aged 69, of cerebral hemorrhage and pneumonia.

Alonzo Leroy Reynolds, Webster Groves, Mo.; Meharry Medical College, Nashville, Tenn., 1927; examining physician for the board of education; served on the staffs of the Homer G. Phillips Hospital and St. Mary's Infirmary, in St. Louis, where he died recently, aged 49, of pyloric obstruction and gastric hemorrhage.

Ralph Dresden Robinson ⊕ Mount Vernon, Ill.; University of Tennessee College of Medicine, Memphis, 1935; past president of the Tillman County (Okla.) Medical Society; member of the Missouri State Medical Association; served during World War II; served as a member of the department of medicine and surgery of the Veterans Administration and assigned to the surgical section of the veterans' hospital in Fort Bayard, N. Mex.; died in the Veterans Administration Hospital, Topeka, Kan., recently, aged 38, of diabetes mellitus.

Neff Lloyd Ross, Colorado Springs, Colo.; Yale University School of Medicine, New Haven, 1946; interned at the University Hospitals; died recently, aged 25, of Hodgkin's disease.

Boyd Willamber Schaffner, Akron, Ohio; Jefferson Medical College of Philadelphia, 1902; member of the American Medical Association; died recently, aged 71, of heart disease.

Charles Edward Seale, Houston, Texas; Louisville (Ky.) Medical College, 1905; affiliated with the Park View Hospital; died recently, aged 66, of heart disease.

Edgar L. Simonton, Wendell, Idaho; Kansas City (Mo.) Medical College, 1896; member of the American Medical Association; died in Rochester, Minn., Nov. 27, 1947, aged 78, of uremia and prostatic hypertrophy.

Edward I. Sloan, Fort Lauderdale, Fla.; Loyola University School of Medicine, Chicago, 1918; formerly associated with the U. S. Public Health Service; served on the staff of the U. S. Marine Hospital in Chicago; died recently in Chicago, aged 64, of coronary disease.

George McClelland Speck, Huntingdon, Pa.; Jefferson Medical College of Philadelphia, 1888; died recently, aged 84, of arteriosclerosis.

Nathaniel L. Spengler, Tampa, Fla.; University of Maryland School of Medicine, Baltimore, 1903; member of the American Medical Association; died in the Tampa Hospital Nov. 28, 1947, aged 69, of myocardial failure.

Seth Billington Sprague ⊕ Jersey City, N. J.; Baltimore Medical College, 1906; fellow of the American Academy of Orthopedic Surgeons; formerly on the faculty of the New York Post-Graduate Medical School and Hospital, Columbia University; affiliated with Hudson County Tuberculosis Hospital, Margaret Hague Maternity Hospital and Christ Hospital; member of the city medical advisory board during World Wars I and II; died in the Memorial Hospital in New York, Nov. 23, 1947, aged 69, of pneumonia.

Frank Bell Steele ⊕ St. Petersburg, Fla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; member and formerly secretary of the Utah State Medical Association; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; served on the staffs of Veterans Administration hospitals in various cities; died recently, aged 73.

Arthur Tumpin Stevens, Tampa, Fla.; Hospital Medical College, Atlanta, 1911; member of the American Medical Association and the Medical Association of Georgia; died in Bay Pines, Nov. 29, 1947, aged 72, of coronary thrombosis.

Henry Barrell Strock, Bedford, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1894; for many years president of the school board; died Nov. 29, 1947, aged 79, of arteriosclerosis.

Harry Alfred Terry, Tampico, Ill.; Washington University School of Medicine, St. Louis, 1904; died recently, aged 69.

Willie Burt Trammell, Lawrenceville, Ga.; University of Georgia School of Medicine, Augusta, 1940; served as health commissioner; died recently, aged 33.

Frank Herbert Underwood, Monongahela, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1894; member of the American Medical Association; affiliated with Memorial Hospital; died in Mercy Hospital, Pittsburgh, recently, aged 78, of cerebral hemorrhage.

Lionel O. Waguespack, Vacherie, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1900; member of the American Medical Association; died Nov. 3, 1947, aged 69.

Bishop Billings Warwick, Talladega, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1902; member of the American Medical Association; past president and secretary of the Talladega County Medical Society; served overseas during World War I; for many years county health officer; staff physician of the Alabama Institute for Deaf and Blind; died in New Orleans recently, aged 68, of coronary thrombosis.

Samuel Melville Waterhouse ⊕ Colonel, U. S. Army, retired, Scarsdale, N. Y.; Medical College of Ohio, Cincinnati, 1894; entered the regular army as an assistant surgeon on July 23, 1898; served during World War I; retired from active service Aug. 6, 1920 for physical disability incident thereto; died in Palm Beach, Fla., Feb. 19, 1944, aged 73, of thrombosis.

Leonard Gruner Weber ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1900; fellow of the American College of Physicians; served on the staffs of Lenox Hill Hospital and the Manhattan Eye, Ear, Nose and Throat Hospital; died Nov. 30, 1947, aged 69, of coronary sclerosis.

W. Frank Wells, Atlanta, Ga.; Atlanta School of Medicine, 1911; member of the American Medical Association; fellow of the American College of Surgeons; twice mayor of Hapeville, Ga.; affiliated with the Grady Hospital and the Georgia Baptist Hospital, where he died Nov. 7, 1947, aged 63, of cerebral hemorrhage.

Charles D. Williamson, Three Rivers, Texas; College of Physicians and Surgeons, Dallas, 1906; member of the American Medical Association; past president of the Bee-Live Oak-McMullen Counties Medical Society; died recently, aged 78, of carcinoma.

Benjamin Franklin Windle, Bois D'Arc, Mo.; Barnes Medical College, St. Louis, 1897; affiliated with the Baptist Hospital in Springfield; died recently, aged 72, of coronary thrombosis.

Elizabeth Mildred Yates, Santa Rosa, Calif.; Cooper Medical College, San Francisco, 1887; member of the American Medical Association; died recently, aged 94, of arteriosclerosis.

Patrick Joseph York, Brooklyn; Long Island College Hospital, Brooklyn, 1897; for many years police surgeon; affiliated with Kings County Hospital, Long Island College Hospital and St. Peter's Hospital, where he died Nov. 25, 1947.

The Struggle over the National Health Service

The greatest crisis in the history of the medical profession in this country is reached as the plebiscite of the whole of its members is taken by the British Medical Association to ascertain exactly the position of the profession with regard to the National Health Service. Reports from all parts of the country suggest, says the *British Medical Journal,* that an overwhelming majority of doctors are radically opposed to the service in its present form. They are convinced that it is the first step toward full time service. However, there is a minority, whose exact size will be ascertained by the plebiscite, who are in favor of accepting the service. This view is advocated by the *Lancet,* while suggesting concessions to meet the objections of the profession. It argues that National Health Insurance, which was introduced in 1913 for only wage earners, against the will of most of the profession, has proved advantageous both to the public and the profession, so that in 1930 the British Medical Association was recommending its extension with improvements. The association is now in favor of this extension in place of the present scheme, but the socialist government on its own initiative and without any opposition has extended free medical attendance of all kinds, domiciliary and hospital, general practitioner and specialist, to rich and poor alike. The *Lancet* holds that there are cogent reasons for this. The cost of illness now falls disastrously on the middle class. The negotiating committee of the profession accepted the inclusion of all, rich and poor. It thus agreed, wisely or unwisely, that the profession must henceforth work within the framework of a public service and no longer depend on private fees.

Evidently with the intention of "throwing oil on the troubled waters" the *Lancet* has submitted nine questions to the Minister of Health, which, with his answers, are published in the *British Medical Journal* as well as the *Lancet.* The intention of the government is that the main source of the doctor's income shall be by capitation. The advantages of the basic salary are that it enables beginners to live while they attract patients and that it affords a convenient peg on which to hang additional payments, such as for sparsely populated areas, and reduces the temptation to try to build up excessively long patient lists.

The sale of practices has been condemned by some reformers, but there are great difficulties in abolishing a custom which is the financial backbone of general practice in this country. In partnerships there usually are agreements that in case of the death or retirement of one of the partners, those who remain are bound to buy the share of the outgoing man. If the sale of practices were abolished a man might be compelled to buy what had ceased to have a commercial value. With regard to the difficulties in the carrying out of partnership agreements produced by the act, the minister proposes to obtain a collective legal opinion. If there is any evidence that existing partnerships are unfairly prejudiced by the act he will seek an amendment. There is no doubt that by compromise, at which the English are known to be so adept, agreement could be reached without much difficulty on the various objections raised by the profession, except the fundamental one of the nationalization of physicians—making them salaried officials. The minister says that this is not proposed now, but that he cannot answer for future ministers of health. However, it is known that this intention is approved by the leaders of the labor party. The government is nationalizing the big industries one after another. It would like to nationalize the medical profession, but practical difficulties oblige it to proceed by steps. A very large one was taken when free medical attendance for all was provided in the National Health Insurance Act, without any opposition from the medical profession. "We are all socialists now," said a great conservative leader, the late Lord Salisbury, who certainly had no sympathy with socialism. The truth of that adage is again illustrated in the present crisis.

The council of the British Medical Association has issued a statement declaring that the decision is of the profoundest importance to the public and the medical profession. The conflict is based on the profession's conviction that the act leads unmistakably toward a whole-time state medical service, which would be harmful to medicine. In the negotiations with the Minister of Health, Mr. Bevan, the representatives of the profession sought some changes, both of principle and of detail, but he refused to modify one word of the act. The council of the medical association will abide by the result of the plebiscite, as defined on the form, but its carefully considered and determined view is that the profession should not take service under the act in its present form.

The opposition of consultants and specialists to the act is just as great as that of general practitioners. In a meeting held at the house of the British Medical Association they rejected the act in its present form by a majority of 766 to 11. Among the speakers, Lord Horder appealed to his fellow consultants to halt the mad march of totalitarianism. "If we yield," he said, "to this concentration of power to one man we shall be selling our heritage and things will get worse." Mr. Dickson Wright, a surgeon, stressed that under the act the medical committees in hospitals would cease to function. Consultants whose services had established British hospitals in their preeminent position would become paid servants without a vote in their administration. A state medical service would require an army of civil servants, which would provide a good living for men who had not to spend six years in qualifying. The following resolution was proposed and carried, 766 to 11: "In the opinion of this meeting, consultants and specialists should not take service until the act has been modified and agreement reached for the good of the profession as a whole." Meetings of the staffs of the great London hospitals—Guy's, St. Bartholomew's, London, St. George's and the Great Northern—have rejected the proposed service by similar majorities, in one case unanimously.

Rejection of the National Health Service by the British Medical Association

A special meeting of the Representatives of the British Medical Association has unanimously passed a resolution that the National Health Service in its present form is so grossly at variance with the essential principles of the profession that it should be rejected absolutely by all practitioners. The *British Medical Journal* says: "Doctors are now fully alive to the implications of the Act and becoming firm in their resolve to say 'No' to a Minister whose method of negotiation is to alternate blandishments with threats in his successful attempt to avoid discussing those matters which the negotiating committee consider fundamental points of disagreement between the medical profession and the Ministry of Health. . . . The medical profession is in a strong position and should be more conscious of the fact. Its services are indispensable to the welfare of the community and will, of course, never be withheld, but it can determine the conditions of its work and insist on maintaining a framework of liberty and freedom which at the same time includes order."

In the negotiations between the medical profession and the government the three main objections to the scheme are the small basic salary for practitioners (in addition to the capitation fees), the abolition of the sale of practices within the service and the refusal of a right of appeal to the courts of law by a doctor dismissed from the service by an official decree. The objection to the basic salary is that it seems to be "the thin end of the wedge" of complete payment by salary, which would convert the practitioner into an official under the complete control of the government. This is the avowed policy of the labor party but has not been pressed for tactical reasons. In the words of the minister of health himself, "one does not pick fruit when it is green, one waits till it is ripe."

Research on the Common Cold

Much research on the common cold has recently been done in this and other countries. At the Royal Society of Arts Dr. C. H. Andrewes, F.R.S., of the National Institute for Medical Research, gave a lecture on the subject. He said that a few clues are now being found as to how colds are spread, what causes them, and how they can be prevented or cured. In ordinary life it is possible to catch cold from much exposure in the presence of a little virus, or from very moderate exposure in the presence of much virus. A trapper in Spitzbergen contracted a cold after contact with a center of civilization. Six weeks later he fell through the ice and his cold returned. The attitude of his fellow trappers was, "silly ass for going into town." Arctic explorers away from civilization caught no colds.

Experiments are in agreement with the idea that resistance to a cold does not depend on when one has had one's last cold but on other factors, not at all understood. Colds are commoner in winter than in summer, but in America instead of the waves of cold traveling southward from the Northern states which have cold weather soonest—the waves occur almost simultaneously from the colder Canadian border down to the Gulf of Mexico. Sudden changes in temperature might precipitate colds more readily in summer than in winter. Cold weather could perhaps act indirectly by making people crowd together indoors, but crowding hardly could be all important, otherwise why do not colds spread in rush hours in tube trains in July? In tests at Harvard Hospital, Salisbury, England, it was found that bacteria-free filtrates from sufferers from colds produced colds in about 50 per cent of subjects. The time from inoculation to onset was usually two or three days. They could store the active agent for over six months at minus 76 C. in carbon dioxide snow and still obtain "takes."

Some recent evidence suggested that more unpleasant germs were spread from the nose than from the mouth and throat, which led to the question whether bacteria and viruses accidentally shaken from handkerchiefs might not be of infective importance. Tests showed that many bacteria might be shaken out and remain in the air. Handkerchiefs used in the later stages of colds were found to be particularly effective as germ distributors. Work now in progress suggests that impregnation of handkerchiefs with a disinfectant might make them much less dangerous in this respect.

The Roentgen Examination of Emigrants

The first of two complete units of x-ray equipment brought to Britain by the Ontario government to facilitate the medical examination of prospective air migrants has been unloaded at the Northolt airport. The unloading was supervised by Dr. G. Clair Brink, director of the division of tubercular prevention, Ontario Department of Health, who was accompanied by Mr. J. S. P. Armstrong, agent general for the province. The units will be set up at the province's air emigration offices in London, England, and Glasgow, Scotland. In an interview Dr. Brink said that the equipment would not only facilitate the medical examination of emigrants but would preclude the possibility of an emigrant with active tuberculosis being separated from his family by delayed detection. Accepted emigrants and members of their families would be examined free.

Florence, Dec. 30, 1947.

Surgical Treatment of Pulmonary Tuberculosis

At a meeting in Naples sponsored by the Sanatorial Institute and the Association for the fight against tuberculosis, Professor Zandonini discussed the combined treatment of endocavitary aspiration and thoracoplasty. In his 9 patients treatment was limited to the use of a cannula and the procedure was not a completely closed one. In 1 patient among those treated a permanent cavity was observed after thoracoplasty, which he attributed to a persistent opening of the bronchus. Research is required, he said, for the removal of this cause of failure.

From his experience and that of others Zandonini concludes that endocavitary aspiration as a preparatory stage for thoracoplasty is the method of choice for the treatment of large cavities of the upper pulmonary lobe. This method offers the advantages of shortening the postoperative course and of providing for a much more favorable prognosis. It reduces the number and the extent of the removal of ribs.

Professor Biancalana of the University of Turin also discussed endocavitary aspiration. In contrast to collapse therapy, it aims to modify the endocavitary conditions, and those of the bronchi for drainage, which have an important part in the closure of the cavity. As yet insufficient time has elapsed to accurately evaluate the method or the associated technical difficulties. It took a long time and laborious adjustment for thoracoplasty to reach its present position as the principal method of collapse therapy. Endocavitary aspiration cannot compete at present with thoracoplasty and extrapleural pneumothorax, which give a recovery rate of about 75 per cent of patients so treated. But there remains a group of patients in whom, because of the grave general condition or the extent of the cavity, collapse therapy is associated with great risk. In these instances the aspiration method as initial treatment seems to be more rational. With aspiration alone one cannot obtain definite closure of a large tertiary cavity, but it is a great advance if one succeeds in reducing the cavity by means of aspiration so that permanent recovery may result from a secondary thoracoplasty or if one considers it safe to carry out surgical intervention in a patient who has first been considered inoperable. Better results have been obtained with thoracoplasty combined with aspiration when the latter was performed prior to thoracoplasty in order to disintoxicate the patient or reduce the extent of the cavity.

The technic of aspiration, which may be carried out easily in some cases, is associated with hazards which can be prevented by continuous care. The application of drainage, the apparatus and the technic, its duration and the choice of the right time for performing the thoracoplasty are all important. The speaker emphasized that the number of his cases is too small to discuss final results.

Professor Biancalana suggested that all surgeons report not only the favorable cases but also the unfavorable ones so that steady improvement could occur with a method which may help some patients, who formerly were not considered suitable subjects for collapse therapy, to be cured by thoracoplasty.

Transmission of Poliomyelitis Virus to Animals

At a meeting of the medicosurgical society of Bologna, Professor G. Salvioli discussed the susceptibility of some animals to the virus of poliomyelitis. The author stated that besides monkeys other species of animals are susceptible to the virus of acute anterior poliomyelitis; his studies at the pediatric clinic and at the antipoliomyelitis center confirm his hypothesis. The cat was the first animal experimented on; after inoculations of various types of virus the animal presented a transmissible fatal syndrome with intestinal manifestations. A paralytic syndrome was exceptional.

According to Professor Salvioli, new fields of study may be opened. The entire epidemiology of poliomyelitis should be reviewed, because innumerable reservoirs of the virus may be considered. Professors Salvioli and Sternini submitted a report of their studies on the transmission of the virus to animals by describing the aspect of the disease in cats after inoculation with virulent material. The inoculation was made by intraventricular, intracerebral or intramucosal route with the Heine-Medin meningitic fluid, or by rectointraintestinal or duodenal route with a suspension of fecal material by means of a tube or by the parenteral route with the filtrate of the same material. For successive passages suspensions of scrapings from the intestinal mucosa or filtrates of such suspensions were employed by the intraintestinal or parenteral route, respectively.

The inoculated cat presented a fatal syndrome which was transmissible to animals. Finally there were obtained three passages with an accentuated or precipitated symptomatology, dominated by severe diarrhea associated with emaciation, asthenia, tremor and mild fever. Death occurred within a few days. These phenomena were not confirmed in controls treated with the cerebrospinal fluid or feces of normal subjects. In 2 instances flaccid paralysis of one limb was observed.

Among the few animals which survived, some were inoculated with virulent scrapings from the mucosa kept in contact with convalescent serum. This fact suggests that in the morbigenous material which has been employed there may have been present an agent which has been neutralized by the serum of subjects convalescing from poliomyelitis.

Views on Iron in Animals and in Therapy

At the Academy of Science in Ferrara, Dr. Tria discussed the distribution of iron in the organs during various periods of life and the significance of iron in relation to various physiologic conditions. The speaker discussed the recent research by Lemberg and his co-workers on the derivatives of hemoglobin with open cycle, the research of Agner on verdoperoxidase and that of Goddard on cytochrome C.

He recalled the modern views on circulating iron, with particular consideration of ferritinic iron, referring to the research by Laufberger, Tria, Kuhn, Granick and co-workers. Finally he summarized the theory by Granick on the physiologic importance of ferritin on the metabolism of iron.

Dr. Rietti discussed iron therapy, emphasizing the action of iron on hemoglobin deficiency and that of plasmatic, nonhemoglobinic iron. He also discussed certain conditions of cellular hyposiderosis characterized by changes of the skin, of its adnexa and of the mucosa which may be influenced by treatment with iron. The use of radioactive iron has opened new means for study of iron and its effect on diseases of various types.

With regard to infectious anemia, the speaker emphasized that one is not dealing with a true anemia of iron deficiency; based on his data on experimental allergy he suggested that the influence of some sensitization may explain the disturbances of metabolism of iron associated with infection.

Iron seems to have an inhibiting effect on hemolysis; there is an increase in anabolic activity in the course of exchange of pigments and a favorable influence may be exerted in some cases of hemolytic icterus with increased globular resistance, of Rietti-Greppi-Micheli type, in which the resorption and the utilization of iron may be prevented by gastric changes of mesenchymal origin.

Compulsory BCG Vaccination

The most outstanding medical event in Norway last month was the adoption by the Storting of a law providing for compulsory tuberculin testing and vaccination against tuberculosis of certain groups in the community who are most in danger of this disease. This law is framed with the contingency in mind that an even more effective vaccine than BCG may ultimately be discovered. Hence the omission of any direct reference to the vaccine by name. But it is, of course, BCG vaccination for which this law provides. The Norwegian Department for Social Affairs, responsible for public health measures, has issued a comprehensive memorandum designed to initiate the country's legislators into the history of, and arguments for, this type of vaccination. A perusal of this memorandum makes it clear why this radical measure against tuberculosis encountered so little opposition in the Storting: one reads how the Norwegian public health authorities consulted everyone concerned before preparing the final draft of the law. Among other organizations in favor of it was the Norwegian Tuberculosis Doctors' Association, which in November 1946 unanimously passed a resolution in favor of compulsory BCG vaccination of youngsters at the time they left school, of conscripts and other young folk much exposed to infection.

In parts of Norway there is considerable opposition to vaccination against smallpox, whereas there is practically no such opposition to vaccination against tuberculosis. Probably this is so because smallpox is little more than a name to the man in the street, whereas everyone knows all too well what tuberculosis means. For example, in 1941, in this country with a population of only 3,000,000, there were more than 21,000 persons under the supervision of the public health authorities because they had infectious tuberculosis.

Diagnostic Possibilities of BCG

Hitherto unpublished investigations conducted at the Ullevaal Hospital by Drs. H. J. Ustvedt and A. Aanonsen suggest that BCG vaccine may be employed as a substitute for the Pirquet and Mantoux tuberculin tests. Through a drop of BCG (20 mg. in 1 cc.) applied to the skin, these investigators make two small punctures with two gramophone needles on a holder. They describe three types of reaction easily distinguished from each other. The first (nonspecific) reaction is rare, appearing in a day and usually disappearing in two or three days. Most interest centers about the second type: Beginning on the second or third day and reaching its maximum on the sixth or seventh day, it consists of a definitely infiltrated, brownish red papule 2 to 10 mm. in diameter. When this reaction is severe, the reaction to the tuberculin test is invariably positive. The third type of reaction appears on the tenth to the fourteenth day and is similar to the ordinary BCG reaction in a tuberculin-negative person.

To return to the second type of BCG reaction, the "positive early reaction," it is an example of Koch's phenomenon; it seems to be a more sensitive and specific test of an active tuberculous infection than the Mantoux test with 1 mg. of tuberculin. It is suggested that BCG thus employed is capable of distinguishing between infected and noninfected persons who are tuberculin-negative. When the Pirquet test is negative and the Mantoux test is positive, this BCG test may decide whether a positive Mantoux reaction is specific or nonspecific. For more than a year these investigations have been conducted on about 400 persons, and it is to be hoped that more will soon be heard of this new use of BCG.

Correspondence

CUTANEOUS STAINS

To the Editor:—The suggestion by Dr. Cornbleet, "Cutaneous Stains Removed with Chemical Depilatories" (The Journal, page 573, Nov. 1, 1947), indicates that an old, convenient, reliable and safe method for removing cutaneous grime and stains is not as familiar to physicians today as it was forty years ago. It used to be, and presumably still is, also in common use by some mechanics, chemists, dyers and others whose work leaves their hands grimy and stained.

It consists of washing with a solution of potassium permanganate, rinsing with water, washing with a solution of sodium bisulfite, $Na_2S_2O_5$ (not bisulfate), and finally rinsing with water until the skin no longer feels slippery.

The potassium permanganate oxidizes the sebaceous and other loose organic matter on the skin, loosening the grime. It also oxidizes and decolorizes practically all organic dyes and pigments including merbromin ("mercurochrome"), sodium ethylmercurithiosalicylate ("merthiolate"), nitromersol ("metaphen") and gentian violet and also hair pigments. It leaves behind a brown stain of manganese dioxide which, if left alone, takes, as Dr. Cornbleet states, days to wear off.

The sodium bisulfite solution reduces the manganese dioxide and dissolves the resulting manganous oxide, leaving the skin clean and smooth. Sulfur dioxide is released in this reaction, giving a noticeable odor, but its concentration is not sufficient to be troublesome. Sodium bisulfite alone will remove iodine stains.

The method used by workmen in cleaning their hands is to pour about a teaspoonful of finely crystalline potassium permanganate into the palm of the hand, moisten it with water and rub it gently around until the hands are wholly covered with the dark brown stain. This is not a scrubbing process. It is merely a convenient method of bringing a concentrated solution into contact with the skin to be cleaned. Scrubbing is not necessary, and hard rubbing is to be avoided because the crystals, like any grit, can, if rubbed on too hard, roughen and even abrade the skin. Particular attention is paid to working the crystals under the finger nails to insure thorough cleansing.

The hands are then rinsed, and finely crystalline sodium bisulfite is applied in the same manner until the brown stain disappears. This ordinarily takes only a few minutes. If the grime and stains have not been completely removed the whole process is repeated. The final rinse until the skin no longer feels slippery removes practically all the remaining sodium bisulfite. I know of no other method which is as effective in cleaning grimy finger nails.

For stains on other body surfaces it is usually more convenient to make up the solutions and apply them by patting with a swab. On delicate skins the solutions should not be concentrated but should be diluted with an equal volume of water. The oxidation of a dye or pigment and the reduction of manganese dioxide release energy in the form of heat. If the solutions are concentrated the heat released may sometimes be sufficient to be uncomfortable on delicate skin and may even cause a temporary erythema, which may last for a day or so. This does not cause permanent damage but is preferably avoided. With dilute solutions it may be necessary to repeat the procedure several times before a stain is completely removed.

There is only one other caution necessary. If used locally on the scalp it leaves an area of bleached hair which may in some cases be more conspicuous than the stain which was removed.

Since solutions of sodium bisulfite have a p_H of about 4 to 4.7, the little that is left on the skin after the final rinse is much less likely to irritate it than the popular, much more acid, "vinegar hair rinse," with its p_H of about 2.

I have been told that if this method is used too frequently it will ultimately irritate the skin. However, I have in the past used the concentrated solutions for cleaning my hands sometimes as often as twice a day for weeks at a time with no resultant irritation.

L. B. Tuckerman, Washington, D. C.

Comment.—The practice outlined in this letter is still used by manufacturing pharmacists, chemists and other laboratorians to remove stains in the course of their work. When solutions of potassium permanganate, $KMnO_4$, (1:100) and sodium meta bisulfite, $Na_2S_2O_5$, are not at hand, they use the crystals and a little tap water receiving the same results. However, sodium thiosulfate ("hypo") is cheaper, less irritating than sodium meta bisulfite. "Hypo" is the active ingredient in iodine stain removers.—Ed.

ARTERIOSCLEROSIS AND DIABETES IN YOUTHS

To the Editor:—The editorial on "Diabetes and Arteriosclerosis in Youth" (The Journal, Dec. 20, 1947, p. 1074) and the article on "The Relationship of Chronic Alcoholism to Arteriosclerosis" by S. L. Wilens, M.D. (The Journal, Dec. 27, 1947, p. 1136) bring the following to mind: In 1934, A. Feller and I reported the results of extensive studies at the International Society of Geographical Pathology in Utrecht, Belgium. The study was based on systematic vascular investigation in 1,238 postmortem examinations made at the University Hospital, University of Vienna, Austria.

It was found that diabetic persons in the higher age groups showed a considerable increase in arteriosclerosis. However, such a difference was not statistically significant in patients below 50 years of age. No difference could be found in this study between alcoholic addicts and controls, considering equal age groups, essentially confirming the findings by Dr. Wilens on a different type of population.

I might mention that in our study there was no doubt that heavy smokers aged above 50 showed a considerable increase of arteriosclerosis, both in the coronary and femoral vessels and in the aorta. Since this study was made under different circumstances, it might be of general interest.

Arthur J. Lesser, M.D., Los Angeles.

URETHANE IN LEUKEMIA

To the Editor:—According to J. J. Webster (The Journal, Dec. 6, 1947, p. 901) available reports on the subject of urethane in leukemia "are chiefly in the British and German journals, and represent an optimistic view as to the future of urethane therapy." As far as the original paper was concerned (Paterson, E.; ApThomas, I.; Haddow, A., and Watkinson, J. M.: *Lancet* **1**:677, 1946), it was certainly not our intention to create any impression of optimism, and we do not consider that such could in fact have been conveyed to the majority of readers. While the palliative effects of urethane were recognized as remarkably similar to those obtained by standard methods of high voltage roentgen therapy, it was on the contrary made clear that no indication had been found "that permanent benefit may result from the use of urethane in either myeloid or lymphatic leukaemia." This goes considerably further than Dr.

Webster, who believes that "urethane has been used for so short a time that the cure, of course, cannot be judged." On the contrary, we have on no occasion encountered any result approaching cure, and should consider the possibility as extremely unlikely.

A later paper by Paterson and associates (in Approaches to Tumor Chemotherapy, American Association for the Advancement of Science, 1947, p. 401) adduces evidence to show that excessive dosage of urethane may bring about serious damage to both the white and red cell series, and ends as follows:

"It must be emphasized that the . . . results provide no indication of any kind that permanent benefit may result from the use of urethane in either myeloid or lymphatic leukaemia: the action of the drug is essentially reversible, relapses take place, and immature cells may reappear in the blood. At the same time, however, it can be said that the palliative effect is in many cases very substantial. It seems probable that the greatest value of the observation lies in its very considerable scientific interest, and in the fresh opportunities which it presents us for further attack."

This seems a fair statement of the position at the moment.

Alexander Haddow, M.D.,
Fulham Road, London S.W. 3.

COMING EXAMINATIONS AND MEETINGS

BOARD OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal Feb. 21, page 575.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I & II.* Various centers, June 21-23. Final date for filing application is May 22. *Part II.* Various centers, April 26-27. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York, April 12-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

American Board of Internal Medicine: *Written.* Oct. 18. Final date for filing application is June 1. Asst. Sec-Treas., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Obstetrics and Gynecology: *Oral. All Groups. Part II.* Washington, D. C., May 16-22. Final date for assignment is April 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Ophthalmology: *Oral.* Baltimore, May 20. Chicago, Oct. 6. *Written.* Various centers, Jan. 1949. Final date for filing application is July 1, 1948. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, January 1949. Final date for filing application is August 15. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: *Oral.* Chicago, June 15-19. Sec., D. M. Lierle, University Hospital, Iowa City, Iowa.

American Board of Pathology: Philadelphia, March 8-10. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis, Mo.

American Board of Pediatrics: *Oral.* Cleveland, April 23-25. Chicago, June 25-27. Seattle, Sept. 10. Atlantic City, Nov. 17-19. *Written.* March 12, July 30. Sec., Miss Lea Leonard, 718 Royal Union Bldg., Des Moines, Ia.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr. Robert H. Ivy, 1930 Chestnut St., Philadelphia.

American Board of Radiology: *Oral.* Chicago, June 1948. Final date for filing application is March 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written. Part I.* October. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Judicial Notice of Need for Roentgenogram in Fracture Case.—The plaintiff sued for damages for injuries received as a result of a fall and as the result of the alleged malpractice of the physician in treating her therefor. From a judgment of nonsuit in favor of the physician, the plaintiff appealed to the district court of appeal, second district, division 2, California.

The plaintiff, a woman 51 years of age, slipped and fell, landing heavily on her right hip. She called the defendant physician, was advised that he was out of the city and was taken instead to the Hollywood Receiving Hospital, and then to her hotel. The next morning she again called the defendant physician. He replied that he had received a report from the Receiving Hospital that she was just bruised and that it was not necessary for him to visit her. He prescribed "anacin," rest and hot baths and told her to call him the following morning. Two days later she again telephoned the defendant physician, told him that she was still in great pain and asked him if he did not think he should come over to see her. He replied in the negative, stating that a bruise was often more painful than break. About a week after the accident, while leaning against a dressing table, the plaintiff's right ankle turned over and she heard her hip bone crack. The house physician in her hotel caused her to be removed to the Cedars of Lebanon Hospital, where roentgenograms were taken, and she was later transferred to the California Hospital, where the defendant physician finally called in person to see her. She told him that the members of the staff at Cedars of Lebanon Hospital thought that her hip was broken, but the defendant physician still adhered to his original diagnosis. Two days later, however, he told her that he had examined the roentgenogram taken at Cedars of Lebanon Hospital and that her hip was broken. Additional roentgenograms were then taken, her leg was placed in a cast and she was hospitalized for twelve weeks. Although the plaintiff was still suffering pain in her hip nine months after the accident, the defendant physician told her that she was not suffering from any necrosis and that the pain was caused by arthritis or neuritis.

It was the defendant's contention that these facts were not sufficient to make out a prima facie case in favor of the plaintiff, since there was no expert medical testimony indicating that the defendant had failed to use the required degree of skill and learning.

The appellate court said that the law requires a physician to have and exercise that degree of skill and learning ordinarily possessed and exercised by physicians of good standing practicing in the same locality. Furthermore, whether or not the physician has done so in a particular case is a question for experts and can be established only by their testimony. To this general rule, however, the court continued, there is a well recognized exception, to wit, where the question of the propriety of a treatment is a matter of common knowledge to laymen, expert testimony is unnecessary in order to establish liability in a malpractice case. The use of roentgen rays as an aid to diagnosis in cases of fracture or other indicated cases, said the court, is a matter of common knowledge of which the court, in the absence of expert testimony, may take judicial notice. When the plaintiff fell, said the appellate court, a possible fracture was indicated, and under the foregoing rules it was a matter of common knowledge, of which the trial court should have taken judicial notice, that the ordinary physician in good standing in this community in the exercise of ordinary care and diligence would have had roentgenologic pictures taken of the plaintiff's body. In failing to do so the defendant did not exercise the degree of learning and skill ordinarily possessed by physicians of good standing practicing in this community. No expert testimony was needed. Accordingly the judgment of nonsuit in favor of the defendant physician was reversed.—*Agnew v. City of Los Angeles, 186 P. (2d) 450 (Calif., 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Dilutions of "Nupercaine" in Spinal Anesthesia.—In an effort to evaluate the clinical effects of dibucaine hydrochloride ("nupercaine hydrochloride") in dilutions greater than 1:1,500, Fisher and Whitacre used concentrations varying from 1:2,000 to 1:10,000 in 1,124 cases, of which all but 61 involved intra-abdominal operations. It was desired to determine the weakest effective dilution necessary to produce anesthesia and to observe whether high dilutions decreased the toxicity of dibucaine. The use of the higher dilutions of the drug for spinal anesthesia indicated that the concentration of the drug did not appreciably alter the degree or duration of sensory anesthesia or motor block. Likewise, the incidence and severity of circulatory reactions were not decreased by the use of dilute solutions of dibucaine. It appears that the toxicity of dibucaine in spinal anesthesia is dependent primarily on the amount rather than the dilution of the drug. There is little or no advantage in using concentrations of dibucaine less than those ordinarily recommended for spinal anesthesia.

Subtotal Gastrectomy for Gastric Ulcer.—Difficulties in differential diagnosis prompted some authors to take the position that gastric ulcer, unlike duodenal ulcer, is primarily a surgical problem. Other writers question the propriety of such a radical attitude, especially with regard to gastric resection. Ransom analyzes his experience of a twenty year period, during which 1,356 patients with gastric ulcer were treated. Of this number, 246 patients required surgical intervention. Twenty patients had acute perforation. Elective surgical procedures were performed in 226 cases. The more conservative operations such as gastroenterostomy have declined. Partial, subtotal or total gastrectomies were performed in 188 cases. Gastric resection has limitations. For patients who are exceedingly obese, who are poor risks or who have high or inaccessible lesions, a less ideal but safer procedure should be selected. With the advent of vagus interruption a new method is available for this group of patients. Subdiaphragmatic vagotomy may be worth while at the time of subtotal gastrectomy in an attempt to prevent jejunal ulcer. The conventional subtotal resection whereby a large portion of the lesser curvature as well as the antrum and pylorus were removed, has given best results in this series. Little difference has been noted in the late results between cases in which a Polya or a Hoffmeister reconstruction was performed and the clinical results of antecolic and retrocolic anastomoses. The Finsterer exclusion operation should be abandoned. The record of results in the 3 total gastrectomies is not good. Although there was 1 excellent result, there was 1 operative death and 1 poor result. The procedure seems much too radical for the treatment of a benign ulcer. The fact that microscopic study revealed cancer in 10 per cent of the lesions, which was not recognized at the time of laparotomy, would indicate that indirect operation for gastric ulcer should be accepted with caution. There is a place for medical treatment in the management of certain gastric ulcers, but its dangers and limitations should be realized.

Pinealomas as Cause of Diabetes Insipidus.—Horrax says that whereas the occurrence of diabetes insipidus in patients with pituitary tumors or other lesions in the suprasellar or chiasmal region was easily understood, the occasional report of polydipsia and polyuria in patients with tumors arising from the pineal body, which is so far removed from the supposed source of diabetes insipidus, was incapable of
Stringer in 1934 studied a patient coming to
in addition to a small pinealoma replacing the

solitary implant confined to the tuber cinereum of the hypothalamus. Diagnosis of pinealoma has been made in 17 instances in his brain tumor series during the past fourteen years. Of these 17 patients, 5 had diabetes insipidus. In 2 of the patients the pineal tumor has been histologically verified and in the 3 other patients the tumor has been demonstrated by neurologic and ventriculographic evidence. In 1 patient (case 1) the tumor cells were shown microscopically to have invaded the hypothalamus and posterior lobe of the pituitary body, thus involving the tract of nerve fibers whose interruption has been shown to be responsible for diabetes insipidus. In case 2 the growth was an ectopic pinealoma in the suprasellar region, obviously compressing the area in question. When the tumor was removed the polyuria was greatly lessened. In the 3 patients whose tumors have been depicted by ventriculography a similar invasion of this tract, as in case 1, seems probable. These 3 patients have received roentgen treatment. In 2 patients the rays were directed not only at the pineal region but also to the suprasellar area, which included the hypothalamic region as well. Their general condition has remained excellent for six and one-half to fourteen years following roentgen therapy. The diabetes insipidus has been considerably relieved in 1 and probably in 2 of these patients. It is possible that the water imbalance may persist, because partial interruption of the nerve tract from hypothalamus to pituitary is permanent even though the tumor cells originally causing this interruption have been destroyed by the roentgen rays.

Cortical Excision in Focal Epilepsy.—Penfield and Steelman show that excision of partially damaged convolutions adjacent to meningocerebral scars or in areas of cerebral atrophy has proved to be an effective treatment of epilepsy. Seventy-six atients submitted to operation. One patient died as a result f the operation. Of the 59 patients who had excision, 15 had no further attacks and 18 had one or two seizures but considered themselves cured or practically so. Of the 16 craniotomies without excision, none were successful. It therefore seems that removal of adhesions, decompression or closure of cranial defects have no effect on the attacks unless the proper excision is carried out. The best results from excision were obtained in the birth injury group. Infectious processes came next and head injury third. Removals in the frontal pole were most successful, and the central (or sensorimotor) cortex came next. When attacks recur early after operation and if the pattern is the same as preoperatively, an immediate second operation should be considered. The persistence of a spike electrographic focus after operation or the appearance of marked delta electrographic activity near the site of removal should cause the surgeon to consider reoperation. In preoperative studies, the simpler the electrographic record is and the better it is localized, the better the prognosis of a successful excision. A well localized, simple electroencephalogram, not supported by pneumographic or other evidence, has sometimes led to a useless exploration. The surest guide to localization of an epileptogenic zone is the seizure pattern. The greatest supplementary help is electrographic study. Radical excision seems to offer a reasonable possibility of cure to those who have cortical foci of discharge and whose attacks are not controlled by medicaments.

*Prostigmine Therapy in Paralysis. E. L. Coodley.—p. 425.
*Treatment of Subacute Bacterial Endocarditis with Penicillin. L. Hyde and B. Hyde.—p. 429.

"Prostigmine" in Paralysis.—Coodley administered neostigmine methylsulfate in a strength of 1:2,000 to 48 patients with paralysis of varying duration. The daily dose was 1 ampule (0.5 mg.) administered intramuscularly with atropine sulfate, grains 1/150 (0.4 mg.). The drug is theoretically indicated because of its effect of neutralizing cholinesterase, thus preventing the breakdown of acetylcholine at the myoneural junction and facilitating the passage of nerve impulses at this point. There is evidence to suggest that neostigmine also acts centrally. The toxic effects of therapy were negligible. There was no correlation between the type of lesion and the therapeutic results. There was a positive correlation between the duration of lesions and responsiveness to therapy. Subacute lesions, those between three and six months, responded to neostigmine therapy; chronic lesions of over six months' duration showed little response. Neostigmine is not a panacea, and partial and complete failures must be expected.

Penicillin in Subacute Bacterial Endocarditis.—The Hydes report 4 patients with subacute bacterial endocarditis caused by Streptococcus viridans who responded to penicillin therapy and are well and asymptomatic. In each case the organism isolated from the blood was found to be sensitive to penicillin in vitro. The daily dose of penicillin received by these patients varied because of the opinions of the individual physicians. The authors believe that at least 500,000 units of penicillin daily for four to six weeks would appear to be effective. A patient not responding should be given a larger daily dose of penicillin over a longer period of time. The first patient received 1,000,000 units every three hours and a total dose of 106,000,000 units.

Sulfapyridine in Dermatitis Herpetiformis.—A questionnaire sent to the members of the American Dermatological Association to determine the present status of sulfapyridine in the treatment of dermatitis herpetiformis revealed that the sulfonamide drugs are of value in the treatment of that disease. Sulfapyridine is the most effective sulfonamide drug in the treatment of this dermatosis. The average initial daily dose of sulfapyridine for this disease is 1 Gm. three times a day, and the average maintenance dose is 0.5 Gm. three times a day. Twelve per cent of the physicians who had experience with the sulfonamide drugs in the treatment of dermatitis herpetiformis had patients who were cured with this form of treatment. All those who had experience with the sulfonamide drugs in this disease stated that, on the average, 80 per cent of the patients had improved to the extent that they were free of symptoms. The physical and mental suffering caused by this chronic pruritic vesiculobullous disease warrants the risk of administration of sulfapyridine. Patients should be apprised of the risk involved. Sulfapyridine has been administered in maintenance doses from three months to seven years with apparent safety. Opinion is equally divided regarding the advantages of continued and interrupted treatment. Mild toxic reactions are frequent. Severe toxic reactions are rare if blood cell counts and urinalyses are made at frequent intervals. Copious intake of fluid and alkali therapy reduce the incidence of these reactions. Penicillin is less effective than the sulfonamide drugs in dermatitis herpetiformis. The antihistaminic drugs are probably an adjuvant to the sulfonamide drugs.

Thiamine and Arsenical Toxicity.—Sexton and Gowdey say that their interest in the relation between thiamine and arsenical toxicity was stimulated in 1943 by the rapid remarkable recovery of a patient in Victoria Hospital, in whom peripheral neuritis and suspected arsenical encephalopathy had developed during the course of the five day drip treatment and after parenteral administration of massive doses of thiamine hydrochloride. The literature revealed that there was an amazing similarity between arsenical encephalopathy and acute vitamin B_1 deficiency. The authors report experiments on animals and observations on patients in whom extensive five day drip arsenical treatment was given. They found that oxophenarsine hydrochloride causes a significant derangement in carbohydrate metabolism, as evidenced by increased pyruvic acid and sugar in the blood. The high level of pyruvic acid suggests that catabolism is stopped at the level of pyruvic acid. This is directly related to the functioning level of thiamine, since a deficiency of the coenzyme containing thiamine produces a high level of pyruvic acid. A sudden rise in the level of pyruvic acid, coinciding with greatly increased muscular sensitivity and rising temperature, is experimental evidence of a reaction of severe toxicity. In a reaction seriously involving the central nervous system vitamin B_1 and 2,3-dimercaptopropanol (BAL), if they are to be used therapeutically, must be given early, before the reaction has gone beyond the irreversible pathologic lesion. Five cases of acute arsenical intoxication are described. In all 5 the level of pyruvic acid was high throughout the course of the drip and the curves portraying this high level of pyruvic acid were all of the same general shape. It would seem that 2,3-dimercaptopropanol and vitamin B_1 in adequate dosage should be complementary in the treatment of arsenical encephalopathy. Administration of vitamin B_1 insures the functioning at peak levels of the cellular enzyme systems not affected by the arsenical. When the usefulness of vitamin B_1 has been exceeded, then BAL may be used to inactivate the arsenical, though this means the loss of its spirocheticidal effect. A high level of pyruvic acid accompanied with clinical signs of subacute B_1 avitaminosis should warrant treatment other than intensive arsenotherapy.

Treponemicidal Action of Arsenic and BAL.—De Orco treated 5 patients who had acute early syphilis with 2,3-dimercaptopropanol, or BAL, and oxophenarsine hydrochloride in an attempt to determine whether BAL effected a depressing action on the treponemicidal factor of arsenic. In 3 cases the destruction of Treponema pallidum was delayed (long after the time normally required with standard treatment) by the use of BAL. In cases 2 and 5 organisms were still present after three and one-half days of injections of combined arsenic and 2,3-dimercaptopropanol. In case 1 T. pallidum persisted for eight days. In one case the T. pallidum quickly disappeared from the lesion following the withholding of one injection of BAL. In another case, in which BAL and oxophenarsine hydrochloride were given simultaneously, there appeared to be no diminution of the treponemicidal action of oxophenarsine hydrochloride; however, based on the other observations it is thought that this was probably due to the different routes of administration of the two drugs, inasmuch as the arsenical was given intravenously, thus allowing for much faster dissemination. Adequate doses of 2,3-dimercaptopropanol have a suppressive effect on the treponemicidal action of arsenic.

Tonsillectomy and Poliomyelitis.—At the May 1946 meeting of the American Laryngological, Rhinological and Otological Society it was suggested that a nationwide survey be carried out with regard to the relationship of tonsillectomy and poliomyelitis. Each section chairman of the society was to appoint one or more members from each state to gather pertinent information for a statistical report. Some members made no report; the reports of others were so sketchy and incomplete as to be useless. Of 6,000 questionnaires received, almost 4,000 had to be discarded. Although this study cannot settle conclusively the problem whether surgeons should avoid removing tonsils during epidemics of poliomyelitis, certain valuable evidence has resulted. One table shows that 4.7 per cent of the cases of bulbar involvement were preceded by tonsillectomies, while only 1.9 per cent of the cases of spinal involvement followed recent tonsillectomies. Not much importance can be placed on the interpretation because of the inadequacy of the original data and the lack of comparative values. Tonsillectomies are performed usually in the summer months, not entirely as a matter of convenience to the surgeons or the children. The summer months, with their low incidence of respiratory infections, offer the ideal time for such a procedure. If the present practice of summer tonsillectomies is to be changed because of fear of poliomyelitis, then the dangers of respiratory infections will substantially increase. To incur that increased risk, laryngologists must have proper justification. Cunning also points out that the majority of tonsillectomies are not elective. Most of them are necessary surgical procedures, performed in the interest of preventive medicine. Infected tonsils are possible etiologic foci for nephritis, mastoiditis, infection of the middle ear, rheumatic fever and many other debilitating diseases. For the full protection of his patient, the surgeon, before postponing an indicated tonsillectomy, must weigh the dangers and the chances of the contraction of any of these diseases as well as the dangers and the chances of poliomyelitis. The author urges that another study be made to answer the question whether children on whom tonsillectomy is performed during the summer months are more likely to contract poliomyelitis than are nontonsillectomized children.

Congenital Atresia of Esophagus.—Perrone and his associates point out that the prognosis of esophageal atretic defects is fatal unless some surgical intervention is accomplished which will prevent pneumonia and starvation, the two primary causes of death. The authors present the histories of 6 patients with congenital atresia of the esophagus who have been observed at the Mercy Hospital in Pittsburgh between 1939 and 1945. Excessive mucus in the mouth and throat was a symptom in all these infants. An example of the dangers of the use of barium sulfate for diagnostic purposes is seen in case 1, in which death occurred soon after barium sulfate had been permitted to enter the bronchi. Iodized oil should be used in preference to barium sulfate, since complications resulting when oil is instilled into the lungs are much less severe than those resulting when barium sulfate enters these organs. The first 3 cases of this series show the necessity of an early closing of a fistula connecting the lower esophageal segment with the trachea. In these 3 cases the gastric contents were constantly being regurgitated upward into the trachea, causing fatal pneumonia. Too frequently the patient is treated for the pulmonary complications for an extended period, and the primary cause of the symptoms is overlooked, as in cases 3 and 6 of this series. Frequently, in view of the regurgitation of feedings, the patient is suspected of having pyloric stenosis, but this confusion should not exist too often. All 6 patients died.

Etiology of Malignant Diphtheria.—Updyke and Frobisher investigated the etiology of malignant diphtheria with reference to the possibility of a synergistic action between Corynebacterium diphtheriae and hemolytic streptococci or other organisms. Two experimental procedures were employed: (1) intraperitoneal inoculation into mice of combinations of living cultures of homologous pairs (both organisms isolated from the same case of malignant diphtheria) of C. diphtheriae and beta streptococci and (2) intracutaneous inoculation into rabbits of diphtheria bacilli or toxin in combination with living cultures of various organisms. In the experiments with mice, deaths occurred in greater numbers and in a shorter time among those animals receiving combinations of sublethal doses of diphtheria bacilli and streptococci than among those receiving the same dose of either organism alone. This was at first interpreted as indicative of a synergistic action between the two organisms. However, it was found that the volume or quality of nutrient material or inert particles, or both, in the inoculum has a decided effect on the lethality of streptococci for mice. The experiments with rabbits in which nonspecific factors in the inoculums were controlled revealed no reactions that could be attributed to synergism between diphtheria toxin and one or more strains of thirty-two different bacteria. The problem of the etiology of malignant diphtheria is as yet unsolved.

Selenium Poisoning.—Rosenfeld and Beath say that inasmuch as selenium contaminates grains and vegetables consumed by human beings as well as livestock the factors which influence selenium poisoning merit consideration. After citing studies from the literature which indicate that dietary factors can reduce and the addition of other chemicals can enhance or decrease the toxicity of selenium, the authors describe studies on the influence of ascorbic acid, beet pectin and potassium iodide on chronic selenate and selenite poisoning. Various amounts of ascorbic acid given by mouth to rats receiving a constant amount of sodium selenite (0.15 mg. selenium) daily did not protect the organs from injury or prevent the development of ascites. The intraperitoneal injection of 28 mg. of potassium iodide daily increased the toxicity of selenate and selenite forms of the element. The daily administration of beet pectin prevented the development of ascites in all but 1 animal during the experiment (eighty days). In animals which were living at the termination of the experiment, however, ascites gradually developed two months after the administration of selenium and pectin was discontinued. Beet pectin did not give complete protection against hepatic damage, and ascites developed due to portal obstruction.

Failure of Peritoneal Button Operation for Ascites.—Welch points out that some of the surgical procedures employed for the treatment of recurrent massive ascites are designed merely to rid the patient of an oppressive volume of fluid; others attempt to eliminate factors in the production of ascitic fluid, and still others attempt to improve the body economy by returning water, electrolytes and protein to the general circulation. To this last group belongs the peritoneal button operation, in which a flanged glass tube is inserted between the peritoneal cavity and a pocket made in the subcutaneous tissues of the anterior abdominal wall. This has the theoretic advantage of providing a constant slow clysis of the patient's own blood transudate and the practical advantage of being a relatively simple operation that can be performed under local anesthesia. The authors describe the histories of 2 patients who were treated with the peritoneal button and in whom the defects were negligible after two to four weeks. Postmortem examination revealed a subcutaneous cystic space having a dense fibrous wall and communicating with the peritoneal cavity in each case. It is suggested that because of the small area of surface exposed and the fibrous character of the wall, little absorption can take place from such a cavity. The peritoneal button operation did not provide an effective, sustained, slow clysis of ascitic fluid in these cases.

Serologic Tests in Syphilis Treated with Penicillin.—Rein discusses the factors which influence the length of time required to attain seronegativity in syphilitic patients treated with penicillin. Generally, patients with secondary syphilis require more time to acquire seronegativity than patients with seropositive primary lesions. In some patients with syphilis there develop more antibodies or reagin than in others after the same type of stimulus. The former patients usually require more time to attain seronegativity. Patients with high serologic titers at the onset of therapy may require more time to attain seronegativity than those with relatively low titers. Certain types of tests may remain positive long after other tests have become negative. The amount of penicillin, the type of penicillin and the length of time required to administer that amount of treatment may also affect the length of time to attain seronegativity. As a rule, the higher the total dosage of penicillin and the longer the period of time during which the treatment is administered, the shorter the time required to attain seronegativity. There are many exceptions to the aforementioned factors. It is of utmost importance to educate patients in the great need of reporting to physicians for serologic and clinical examinations at regularly monthly intervals for at least one year following the completion of penicillin therapy. These examinations are important as a guide to response to treatment, as a means to differentiate between serologic relapse and reinfection, as a means to predict an impending clinical relapse and as a means to detect masked syphilis following a concomitantly treated gonorrheal infection.

Treatment of Warts.—This analysis by Fisher and Chamberlain includes all patients who were admitted to the Radiation Therapy Department of Temple University Hospital from 1931 to June 1945 for treatment of warts. The authors compare roentgen therapy with that of vitamin A, on the basis of 315 cases. Because chronic ulcers have sometimes developed after roentgen therapy for warts, physicians should be interested in methods that are free from danger of such sequelae. Oral administration of vitamin A, 100,000 units per day, is followed by disappearance of the wart in an encouraging percentage of cases. When the wart is situated on the plantar surface of the foot, the likelihood of cure and the patient's comfort are both enhanced by generous use of a callus file (a wooden stick covered with emery particles). When vitamin A therapy fails and roentgen therapy is resorted to, treatment should be limited to an extremely small area by using a shield of metallic lead in which a small hole has been cut, of the order of 2 to 4 mm. in diameter. Repeated applications of roentgen rays are particularly to be avoided. Sequelae such as chronic ulcers do not follow single applications, even with large doses. Furthermore, results with single applications of 1,500 to 3,000 r are at least as good as those obtained with multiple applications.

Carcinoma of Prostate Gland.—The 135 cases of prostatic carcinoma reviewed by Buchert and his associates represent 13 per cent of the total number of patients with prostatism treated during an eight year period. Carcinoma of the prostate is an insidious disease which usually does not cause symptoms until it is far advanced. Thirty per cent of the patients had demonstrable metastatic lesions when first examined. In 81 per cent of the patients the diagnosis was made or suspected following digital examination. Cystourethroscopic examination, roentgenologic studies for metastasis and serum acid and alkaline phosphatase studies are useful adjuncts. Radical perineal prostatectomy is the treatment of choice in selected cases. According to the best authorities, it is justified in 5 per cent or less of the patients. Obstructive symptoms can be satisfactorily relieved by transurethral resection of the obstructing tissue with minimal risk to life. Carcinoma of the prostate carries with it a poor prognosis. Fifty per cent of the patients who died did so during the first twelve months after seeking treatment. Bilateral orchiectomy and the administration of estrogens or both seem to be the treatment of choice for the relief of pain secondary to osseous metastasis. In patients with retention of urine transurethral resection followed by bilateral orchiectomy or estrogens or both seems to constitute the best treatment now available regardless of the presence or absence of demonstrable metastatic lesions. In patients without urinary obstruction orchiectomy and estrogenic therapy seem to be adequate.

Bagasse Disease of the Lungs.—According to LeMone and his associates inhalation of bagasse dust, derived from sugar cane after it has been crushed and the juice extracted, incites a pathologic process which has been termed "bagasse disease of the lungs" or "bagassosis." Bagasse is being used extensively in the manufacture of insulating building materials and refractory brick. It constitutes a serious industrial hazard unless properly handled. About two months of exposure to the dust are required before symptoms appear. The disease manifests itself as an acute febrile illness with extreme shortness of breath, a persistent cough with scanty mucoid sputum and profound weakness. The onset is insidious and gradual. Pulmonary changes incited by the inhalation of bagasse dust consist in a diffuse infiltration and consolidation, an acute bronchiolitis or pneumonia that is similar to that seen in pneumoconiosis but in one respect is greatly different. It is a reversible reaction, with the process undergoing resolution and the lung regaining its normal appearance on the roentgenogram. The etiologic basis is still obscure. Whether or not the pathologic reaction is due to fungi, bacteria or a virus associated with the dust, to an allergic response to the bagasse or its possible infectious agents or their products, to some chemical or physical property of the dust or to any combination of the foregoing factors has not been determined and is still under investigation.

Calcification of Cerebral Ganglions.—Camp says that, to date, at the Mayo Clinic, 12 cases of symmetric calcification of the cerebral ganglions have been observed in which there was definite clinical evidence of parathyroid insufficiency and tetany. In 1 case the calcification followed a thyroidectomy at the age of 19 years; in the other 11, the disease was of the spontaneous type. The pathologic basis for the roentgenologic changes is a colloid deposition in and around the finer cerebral blood vessels with subsequent calcification of the deposits, which coalesce and form vascular sheaths and concretions. Because of the rarity of spontaneous parathyroid insufficiency and the observance of 11 such cases in which symmetric calcification of the cerebral basal ganglions was observed, the author believes that the association of the two conditions should be emphasized. It is possible that some cases of cerebral calcification associated with mental deterioration and convulsive seizures reported in the literature may have included a parathyroid insufficiency. All patients with chronic parathyroid insufficiency should have a roentgen examination of the skull. In addition, a determination of the concentration of serum calcium should be made to establish or exclude parathyroid insufficiency in all cases in which roentgenograms show symmetric calcification of the cerebral basal ganglions. Treatment of the parathyroid insufficiency effects improvement in the mental condition and stops the convulsions without producing changes in the cerebral calcification; this suggests that the latter condition is not responsible for the mental deterioration.

Emphysema as Sign of Bronchogenic Carcinoma.—Rigler and Kelby think that obstructive emphysema has been insufficiently stressed as an early roentgenologic sign of bronchogenic carcinoma. This obstructive emphysema, which results from partial obstruction of the bronchus by the tumor, is best demonstrated by roentgenograms or fluoroscopic examination made during expiration. The transition from emphysema to atelectasis as the tumor grows and completely obstructs the bronchus may be readily determined by repeated roentgen examination. Five cases are reported in detail and 2 partially to illustrate the importance of these observations. Patients suspected of bronchogenic carcinoma but without frank roentgen evidence should always be examined in expiration as well as inspiration. Careful attention should be given to minor differences in radiability of the two lungs to determine whether obstructive emphysema is present. Such a determination should lead to further investigation by bronchography, planigraphy and bronchoscopy.

Cervical Ribs and the Scalenus Anticus Muscle.—Reviewing his twenty-two years of experience in the treatment of symptoms produced by cervical ribs and the scalenus anticus muscle, Adson emphasizes the importance of the vascular test which indicates whether the volume of the pulse has been altered. It has been his experience that little is accomplished by scalenotomy unless the result of the vascular test is positive. He discusses the embryologic formation of supernumerary ribs. their incidence, etiologic factors and the symptomatology. His review of scalenotomy includes the 142 patients for whom scalenotomy was performed at the Mayo Clinic during the twenty-two years from 1925 to 1946 inclusive. He differentiates three groups. The first includes patients for whom scalenotomy was performed without resection of cervical ribs (63 patients). Group 2 includes patients for whom combined operations were performed, that is, scalenotomy and resection of cervical ribs by the anterior approach (26 patients). Group 3 includes patients for whom scalenotomy was performed in the absence of cervical ribs (53 patients). The results obtained in the latter group were not as favorable as those obtained in the first two groups. The author concludes that the treatment which he described in 1927, that is, scalenotomy and sectioning of the insertion of the scalenus anticus muscle, occasionally with resection of the distal portion of the muscle when the muscle is decidedly hypertrophied, constitutes the operation of choice. A combined operation, scalenotomy and resection of cervical ribs, is indicated when the cervical rib is completely formed and is situated high in the neck so that the brachial plexus must ride over the rib in its course into the axilla. Subtotal resection of the cervical rib can be accomplished with the use of a rongeur, through the same wound, by separation of the middle and lower trunks of the brachial plexus.

Early Carcinoma of Cervix Uteri.—Gurskis, Beaver and Nelson obtained slide files of the laboratory of Woman's Hospital and of the department of pathology of Wayne University College of Medicine in Detroit. A total of 15 were selected from several thousand cases. Nine of these did not disclose invasive carcinoma elsewhere in the cervix, and 6 revealed early invasive carcinoma in the same cervix. The criteria of early noninvasive carcinoma were interpreted as possessing the following characteristics: 1. The squamous epithelial cells had a decreased amount of cytoplasm with deeply stained oval nuclei. These changes were found in all 15 cases. 2. All cells of the epithelium resembled each other closely from the basal to the uppermost layer so that the basal layer was not distinguishable. This change was observed in 12 cases. 3. In all cases there was an increase in the number of cells of the stratum germinativum. 4. In 14 cases mitotic figures were present. 5. The basement membrane was not penetrated in any of the noninvasive cases. 6. The subepithelial tissue in all cases was infiltrated with lymphocytes. 7. Seven of the cases disclosed a line of demarcation between normal and carcinomatous epithelium. In 3 of these the transition was gradual, and in the others the demarcation was abrupt and distinct. 8. All 15 cases showed a loss of polarity of the cells. 9. The changes of early carcinoma were also found in areas of coexistent metaplasia in 8 cases. Usually the epithelium overlying these areas was involved in the same process. 10. In 2 cases leukoplakia existed in conjunction with the changes of early carcinoma in the surface epithelium. In 1 of these 2 cases invasive carcinoma was disclosed in some areas. The authors conclude that the results of their studies corroborate the earlier work of Rubin, Meyer, Schiller, Broder and others to the effect that cellular changes, which are regarded as the early manifestations of malignant transformation, develop in the surface stratified squamous epithelium of the portio vaginalis of the cervix. These changes occur before there is invasion and before there is clinical evidence of carcinoma.

Papillary Carcinoma of Thyroid.—Crile reviews observations on 21 patients with papillary carcinoma of the thyroid and lateral cervical region. All patients have been followed from five to twenty-one years, or until their death, and only 3 have died from cancer after they had lived for nine, fifteen and nineteen years, respectively, after the original thyroidectomy. One patient who has refused all treatment is well twenty-seven years after the appearance of the lateral cervical nodules and twenty-one years after these nodules were proved to be papillary tumors of the thyroid. In judging the results of treatment of papillary carcinoma of the thyroid the usual five year period is meaningless. In 16 consecutive patients with papillary tumors of the lateral cervical region, when the thyroid was carefully examined a primary tumor in the thyroid was found. The lateral cervical nodules are probably metastases from a tumor of the thyroid rather than, as was previously believed, primary tumors of congenital origin. Lateral cervical tumors may continue to form until the primary tumor in the thyroid is removed. After this no more lateral cervical nodules appear. In the few cases in which roentgen therapy has been given the results have been disappointing. Results of excision of the primary tumor and the lateral cervical and mediastinal metastases have been excellent. The lateral cervical nodules seldom invade muscles or blood vessels, and block dissection of the neck is therefore not necessary. Since most of the patients are young women, it is an advantage to perform the operation through a thyroidectomy incision or, in the more extensive cases, through an incision parallel to the sternomastoid. The tumor in the thyroid may be small and often is not palpable preoperatively. It usually is scarred or calcified and may not enlarge appreciably over many years in spite of the fact that it continues to give rise to lateral cervical metastases. The primary tumor in the thyroid and the lateral cervical and mediastinal metastases should be excised.

*Methyl Salicylate Poisoning: Report of 2 Cases and Review of Literature. J. J. Cancelmo Jr.—p. 1077.

Bladder Management Following Spinal Injury.—Veseen and his associates assert that genitourinary complications are the chief causes of the high morbidity that follows injury to the spinal cord. They discuss the neural anatomy of the bladder and stress that the ultimate aim of the urologist is to assist nature in producing the return of normal bladder function or the closest alternative, the automatic bladder. The authors outline a program for management which has been successful in their experience.

Renal Decapsulation.—Lowe says that renal decapsulation has been almost completely discredited in recent years, undoubtedly because this procedure was employed in conditions which did not and could not respond to it; however, decapsulation appears to be gaining a little of its previous acceptable standing as surgeons obtain favorable results with it in treatment of cases of anuria and oliguria. The author reports the case of a man who had ingested a "can" of oxalic acid two hours previously in a suicidal attempt. This case of chemical nephrosis caused by ingestion of oxalic acid did not respond favorably to medical treatment, but developed into anuria, alarming edema and nitrogen retention despite the administration of large amounts of fluids intravenously. Immediately after bilateral decapsulation, the kidneys began to function, secreting 1,240 cc. of urine in the first twenty-four hours postoperatively and 2,000 cc. in the second twenty-four hours. Urinary output was normal thereafter. Blood urea nitrogen began to fall immediately after the operation, and returned to normal. The urine cleared after the operation. It is concluded that the anuria was relieved by decapsulation of the kidneys, indicating that the operation has merit in selected cases.

Methyl Salicylate Poisoning.—Cancelmo presents 2 cases of acute methyl salicylate poisoning with a brief review of the literature. The 2 seamen whose cases are reported had drunk the contents of a bottle containing 120 cc. of oil of wintergreen because it tasted good and they thought that there was alcohol in it. One of the men had ingested about 90 cc. and the other one about 30 cc. The latter survived, but the former died in spite of the fact that some of the fluid had been aspirated. The author says that convulsions, fever and pneumonia present therapeutic problems. Until the conflicting views regarding the physiochemical changes are settled, one should treat these patients symptomatically, following the chemical changes in the blood and urine as well as possible and treating accordingly. There is clinical evidence to warrant and experimental evidence to substantiate the use of sodium bicarbonate, intravenous fluids (dextrose, saline and lactate solutions), vitamin K, calcium gluconate and sedatives in the treatment of salicylate intoxication. Methyl salicylate is a potent and fairly rapidly acting poison. Bottles containing this drug should be clearly labeled "poison."

Penicillin in Suppurative Lesions of Brain.—Cairns shows that the access of penicillin to contaminating or infecting bacteria is important particularly in the central nervous system, not only in brain wounds and abscesses but also in pyogenic meningitis, in which blockage of the cerebrospinal pathways may interfere with the spread of penicillin injected intrathecally. In the first 16 cases of pneumococcic meningitis treated with intrathecal penicillin, sulfonamide compounds were withheld, and there were 12 recoveries. Thereafter sulfonamide drugs by mouth were always combined with penicillin, since the two drugs are not antagonistic and the preadmission history in the majority of cases has clearly shown the beneficial effect of sulfonamide compounds. In adequate oral or systemic dosage these drugs, in particular sulfadiazine, usually control the symptoms of pneumococcic meningitis, at least for a time. The author reviews the results of treatment in pneumococcic and meningococcic meningitis, purulent pachymeningitis and brain abscess. He concludes that penicillin is not miraculous in its effects. Given access to sensitive organisms it will assist in their destruction only so long as its concentration remains adequate; but when it has disappeared from the infected area, organisms multiply once more and attack the tissues with their original virulence. The use of penicillin therefore demands a greater degree of precision and planning than has been accorded to less powerful remedies.

BCG in Control of Tuberculosis.—Wilson reports investigations in which a control group of persons was studied along with a group that was vaccinated with BCG (Bacillus of Calmette and Guerin). He concludes that the documentary evidence so far available is insufficient to allow an estimate of the degree of protection it affords or even to prove conclusively that, in a civilized population, it has any protective effect at all. Some of the disadvantages of BCG vaccination are enumerated, and it is argued that, unless the gains from its use are likely to be substantial, BCG vaccination may not be worth while. Since the risk of dying from tuberculosis in the first year of life is so small, universal vaccination of infants is out of the question, and vaccination, if it is used, should be restricted to specially exposed groups like nurses, medical students and children in tuberculous families. It is doubted whether the relative degree of immunity that might be conferred by BCG vaccination would have any greater effect in lowering the mortality than measures designed to shield nurses against undue risk of exposure to tuberculous infection. Since the normal antibody-producing mechanism does not seem to reach maturity till toward the end of the first year of life it might be advisable, if BCG is to be used, to remove the infant from its tuberculous home at birth and delay vaccination with BCG till it is at least 6 months of age.

Staphylococci Resistant to Penicillin.—Barber shows that the incidence of strains of Staphylococcus pyogenes that are grossly resistant to penicillin is increasing rapidly. In a previous study out of a series of 200 patients yielding cultures of Staph. pyogenes penicillin-resistant strains were isolated from 25 (12.5 per cent). In analyzing a series of 100 patients with staphylococcic infection between February and June, 1947, it was found that as many as 38 yielded penicillin-resistant strains. In some cases the penicillin-resistant organisms are present in the original lesion but overgrown by sensitive strains until penicillin treatment leaves them a clear field by getting rid of the latter. Hospital infection with Staph. pyogenes is, however, fairly common, and, penicillin-resistant staphylococci occur far more often in patients who have been in hospital some time than in new admissions. In any hospital using large quantities of penicillin bacteria resistant to its action are probably increasing at the expense of those that are sensitive, and it seems not impossible that in time the resistant organisms will be the sole survivors. That a penicillin-resistant strain of Staph. pyogenes once it has got a footing in the hospital may spread from patient to patient is well illustrated by a series of cases occurring in a unit of the author's hospital. The best method for the detection of penicillin-resistant bacteria in specimens sent to the laboratory is to plate out the infected material direct onto a penicillin ditch plate, using a concentration of about 10 units of penicillin per cubic centimeter of agar in the ditch.

Prothrombin Response to Vitamin K as Liver Function Test.—The observations presented by Wahi are the result of his efforts to correlate the hepatic function tests with observations in biopsy of the liver. During these studies, which included all types of disorders of the liver, it became obvious that all such patients had hypoprothrombinemia, which showed a varying response to parenteral administration of vitamin K. In cases with intense jaundice there is a low level of plasma prothrombin. If after administration of vitamin K there is a rapid return of the prothrombin level to normal, the jaundice is likely to be obstructive, while if the response is poor, a parenchymatous lesion is present.

"Pitressin" Hydration Test in Diagnosis of Epilepsy.—According to Cappon the differentiation between epilepsy and hysteria is often difficult. He cites the case of a young soldier who presented most of the clinical criteria of hysterical fits:

a poor psychiatric background, a psychopathic personality, witnessing fits before, fits occurring always in the presence of other persons without severe injury, no incontinence, atypical convulsions, the fits starting fairly late in adolescence. The "pitressin" hydration test was employed by giving an initial dose of 0.5 cc. of a "pitressin" preparation intramuscularly, with 300 cc. of water orally and subsequently at two hour intervals injections of 0.25 cc. of the drug followed by 300 cc. of water. A total of ten injections was given. An intake and output chart showed the antidiuretic effect with retention of water. The body weight was increased by 2 per cent. After the fifth injection the patient had an epileptiform convulsion. Thus the "pitressin" test proved the existence of epilepsy, and effective treatment was instituted. The author stresses that in the absence of facilities for electroencephalography the "pitressin" hydration test may be found useful in the diagnosis of epilepsy.

*Calciferol in Treatment of Chilblains. S. T. Anning.—p. 794.

Calciferol in Chilblains.—Anning points out that calciferol has been widely advertised as effective in the treatment of chilblains. The author compared the incidence of chilblains during last winter in 103 patients who received calciferol in large doses for lupus vulgaris, sarcoidosis and the like with the incidence in 159 patients not given calciferol. There was no statistically significant difference between the test and control groups as regards the incidence of chilblains. These results suggest that calciferol is ineffective in preventing chilblains. Calciferol appears to have no effect in the treatment of chilblains, since chilblains developed and persisted about the same length of time in all the groups. As treatment with calciferol in high dosage is not without danger, it would be as well if its use for chilblains were discontinued.

Persistent Pulmonary Collapse After Artificial Pneumothorax Treatment. B. Couts.—p. 252.

Endocavitary Aspiration.—Monaldi cites physiopathologic and clinical aspects of cavity formation which led him to develop his method of endocavitary aspiration. He cites cases which illustrate the efficacy of the method when employed either alone or in conjunction with surgical collapse therapy. Statistics analyzing the good results and the failures are lacking, chiefly because records have been lost during the war. If the intracavitary suction method is applied with a rigorous and careful technic it entails no dangers. When it is accompanied by collapse treatment it widens the field of therapeutic possibilities, because many patients who could not be operated on without this method may now be treated. It simplifies the application of thoracoplasty by making it more limited, by improving the conditions under which it is performed and by considerably raising the percentage of successful operations. The autonomous endocavitary aspiration method has a wide application. It will be fully developed only when it is possible to solve the technical problem concerned with the closure of the draining bronchus. The documentary evidence to date concerning the therapeutic possibilities of this method used alone consists of approximately 100 patients who work, enjoy perfect health and display no symptoms of illness.

Sprengel's Deformity.—Spira and Axer describe Sprengel's congenital upward displacement of the scapula in 2 boys, aged 10 and 5 years, respectively, and in a girl aged 13. In 1 patient the condition was corrected by a new surgical technic. The plan of operation fell into three phases: (1) widening the shoulder girdle; (2) lowering the scapula and removing the omovertebral bone and (3) fixation of the lowered scapula. The functional result of this operation was excellent, but cosmetically it was only satisfactory. The authors suggest further technical improvements in the operation.

Ollier's Disease and Its Relation to Other Forms of Chondrodysplasia. A. Langenskiöld.—p. 93.

Early Signs of Tuberculous Spondylitis.—Hagelstam says that tuberculous spondylitis does not always become evident in roentgenograms; large vertebral foci were found at necropsy when roentgenograms were negative. In the course of the methodical examination of roentgenograms of 59 patients with tuberculous spondylitis he observed in some a backward displacement of one or more vertebrae before the tuberculous vertebra had collapsed, the process having been localized to the lumbar spine. He reports histories of several of these patients and concludes that an instability between the vertebrae in the lumbar part of the spine arises early in the clinical course of tuberculous spondylitis as well as with degeneration of a disk. In the roentgenogram this instability might show itself as a retroposition and might occur before any tuberculous changes in the vertebra itself are visible. When tuberculous spondylitis in the lumbar part of the spine is suspected the retroposition of a vertebra favors the belief that the process is to be found in either vertebra adjacent to the injured disk.

*Lumbopubic Electroshock in Therapy of Essential Enuresis. A. Pacifico. —p. 401.
*Penicillin in Therapy of Amentia. G. Zanetti.—p. 447.

Lumbopubic Electroshock in Essential Enuresis.—Lumbopubic electroshock consists of placing electrodes over the cutaneous segments corresponding to the second lumbar vertebra and pubic symphysis, and passing an electric current of 200 or

300 milliamperes (80 volts) for one tenth of a second. The treatment was administered to 11 children between the ages of 6 and 8 years and 1 youth of 16 years of age with nocturnal and diurnal enuresis. None of the patients had syphilis or spinal, urethral or vesical organic changes. Three patients in the group had epilepsy; treatment for enuresis failed in these cases. Shock therapy was given every other day up to a total of three or four. Enuresis was controlled from the first shock treatment in all cases, with the exception of the patients with epilepsy. The latter were given a daily additional shock treatment for six more days, without any effect. The treatment was well tolerated and presented no contraindications. The effect persisted for two months after discontinuation of treatment. This is a preliminary report.

Penicillin in Amentia.—The author resorted to penicillin therapy for five consecutive days in 5 cases of amentia of infectious origin. There was acute delirium with hallucinations or stupor, irregular fever, pronounced dehydration, anemia, gastrointestinal disorder, rapid loss of weight, dissociation between pulse and temperature, hypotension and oliguria. Complete recovery of the patients was obtained.

*Factor in Serum, Increasing Erythrocyte Respiration. J. Pirwitz. —p. 263.

Effect of Insulin on Thyroid, Anterior Lobe of Pituitary Gland and Adrenal. E. Schulze.—p. 265.

*Range of Output of Heart Muscle with Pathologically Lowered Frequency: Conduction Disturbances of Various Degrees. H. Stollreiter.—p. 269.

Correlation Between Serum, Periston and Congo Red. R. Schubert and E. Wiegandt.—p. 273.

Increased Erythrocyte Respiration.—Pirwitz prepared a mixture in physiologic proportion of the serum of patients with anemia whose blood was strongly regenerating, and of erythrocytes of normal persons. The respiration volume of the mixed fluid was increased proportionally to the number of reticulocytes in the blood from which the serum was obtained. A powder was prepared from a dried mixture of equal parts of centrifuged erythrocytes of 10 normal persons. By adding this powder to the patient's serum definite conclusions could be drawn as to the intensity of the respiration-increasing factor in the serum of any patient. Additional experiments made it likely that the factor in the serum which increases the oxygen consumption of the erythrocytes may be identical with an erythropoietic factor in the serum which has previously been described by the author.

Heart Muscle and Pathologically Lowered Frequency.—Stollreiter studied the circulation of 7 patients between the ages of 40 and 70 years in whom disturbances of conduction of various degrees were demonstrated by the electrocardiogram. Three patients had a total heart block and 4 patients had a partial heart block. Central and peripheral slowing of frequency with 24 to 40 beats was predominant. In partial as well as in total heart block the heart muscle reacts to a lowered frequency which has continued for some time with dilatation and hypertrophy (increase in cardiac output and heart action, dilatation of the heart chambers due to enlargement of the heart to both sides). Decompensation of the heart with obstruction of the pulmonary circulation need not be present, although the myogenic reserves may be heavily taxed with it at rest. The minute volume at rest corresponded to the norm in 6 patients, and only in 1 patient was it reduced about 30 per cent. Increase in blood pressure was manifested frequently and corresponded to the large cardiac output. By placing an extra load on the heart the reduced output of the cardiac muscle could be demonstrated in those cases in which it was not yet evident at rest. Examination in standing position revealed reduction of cardiac output up to 68 per cent, which may be explained by the damage to the heart muscle in addition to the effect of the extracardiac regulation. This becomes even clearer with muscular work (turning work on the ergometer) when the highest increase in cardiac output may be only 37 per cent as compared to that of several hundred per cent in normal persons. Analysis of the circulation thus provides an explanation for the clinical picture associated with pathologically lowered frequency. Although the cardiac muscle of these patients at rest is taxed several times more heavily than that of the normal persons, decompensation by no means results at rest. It is obvious that with the changed mechanics of the heart and of the circulation treatment of decompensation of the cardiac muscle may be inadequate and only temporarily effective.

*Syndrome of Thrombosis of Posterior and Inferior Cerebellar Arteries. A. V. Di Ció, G. A. Lista and J. Remolar.—p. 2040.

Syndrome of Thrombosis of Posterior and Inferior Cerebellar Arteries.—The syndrome of thrombosis of the posterior and inferior cerebellar arteries is rare. It is more frequent in persons in the sixth decade of life. Thrombosis of cerebellar vessels, with either arteriosclerosis or atheromatous lesions, and syphilitic cerebellar arteritis are the most frequent causes. The symptoms are anesthesia and pain in the area of distribution of the trigeminal nerve, paralysis of the vocal cords, pharynx and velum palatinum, disorders of deep sensibility of the extremities and cerebellar symptoms. The contralateral symptoms are those of sensory disorders of the trunk and extremities, with dissociation of the syringomyelic type. The complete syndrome is definitely established several hours after sudden appearance of the first nervous symptoms (mainly trigeminal pain and trigeminal anesthesia to temperature). Decided spontaneous improvement occurs in the majority of cases. The treatment is symptomatic. Good results are obtained from antisyphilitic treatment when the syndrome is of cerebellovascular syphilitic origin. A certain degree of invalidism remains after disappearance of the syndrome. A final cerebral vascular accident always occurs within a period of time which varies between five and six years. The author reports a case in a syphilitic man aged 59 years. Spontaneous recovery occurred before administration of antisyphilitic treatment. Improvement became pronounced after antisyphilitic treatment.

*Agranulocytosis Provoked by Thiouracil. J. Solis and T. C. Minnhaar. —p. 733.

Thiouracil Agranulocytosis.—Hemograms were repeatedly made in the course of thiouracil treatment of 2 patients with hyperthyroidism. Both patients were women 53 years of age. In the first case the hemogram showed agranulocytosis on the twenty-second day of thiouracil treatment. The drug was discontinued although definite clinical symptoms of agranulocytosis did not appear. In the second case clinical symptoms of acute agranulocytosis appeared in the course of the third month of administration of the drug. The hemogram was normal the day before the appearance of agranulocytosis, although there was relative leukopenia. It was of the agranulocytic type two days later. Penicillin was successfully administered in both cases. Solis and Minnhaar emphasize: (1) the importance of repeated hemograms in the course of thiouracil treatment; (2) the unusual occurrence of a normal hemogram before appearance of agranulocytosis; (3) the significance of leukopenia (even under 4,000 leukocytes) as a warning of possible changes in the blood, and (5) the value of penicillin treatment and discontinuation of thiouracil.

Book Notices

Hodgkin's Disease and Allied Disorders. By Henry Jackson, Jr., A.B., M.D., Assistant Professor of Medicine, Harvard Medical School, Boston, and Frederic Parker, Jr., A.B. M.D., Associate Professor of Pathology, Harvard Medical School. Oxford Medical Publications. Cloth. Price, $6.50 Pp. 177, with illustrations. Oxford University Press, 111 Fifth Ave., New York 11, 1947.

Professors Jackson and Parker of Harvard are admirably qualified for this pathologic and clinical study of Hodgkin's disease and of related primary neoplasms of lymph nodes. This book represents the fruits of long study of a wealth of material, and its compilation obviously has been a labor of love.

The diagnosis of Hodgkin's disease must rest on a properly executed biopsy where the essential feature is the presence of Reed-Sternberg cells. The authors believe that Hodgkin's disease should be divided into three types, paragranuloma, granuloma and sarcoma, because the pathologic picture, clinical aspects and prognosis differ in each type; however, transition forms of these types occur. Paragranuloma is confined to lymph nodes and has a complete lack of invasiveness, but Hodgkin's granuloma, a more virulent disease, may involve and infiltrate any organ. The authors are of the opinion that the evidence bespeaks an infectious or inflammatory process for the first two forms, whereas Hodgkin's sarcoma behaves as a true tumor. These opinions are not apt to be widely adopted *in toto*, since the three forms of Hodgkin's disease which the authors describe can be more simply conceived as the same disease developing at different rates from slow to fast, respectively.

The authors cultured a small gram-positive anaerobic gas-forming bacillus from the lymph nodes in a "considerable number" of cases of Hodgkin's disease. They wisely refrain from implicating this organism as the etiologic agent of the disease, which, as they state, has yet to be discovered. Their advocacy of the inflammatory nature of Hodgkin's disease, however, is not in accord with the opinion of most workers, who in increasing numbers regard the disease throughout as a neoplasm.

Two of the most interesting present developments in Hodgkin's disease have been the observations of Grand and other members of the Chambers' school who found that extracts of lymph nodes involved by this disease have a necrotizing effect on cells in tissue culture due to a filtrable agent; this work is not discussed. Also, the nitrogen mustards have been extensively investigated as therapeutic agents in Hodgkin's disease, and it is unfortunate that Jackson and Parker have had no personal experience with these materials.

In addition to Hodgkin's disease, which comprises about two thirds of the volume, there are chapters on reticulum cell sarcoma, lymphosarcoma, lymphocytoma, giant follicle lymphoma, plasmocytoma and endothelioma. At the end of each chapter there is a series of magnificent plates illustrating the microscopic anatomy and roentgenographic features of the diseases discussed.

The Problem of Fertility: Proceedings of the Conference on Fertility Held Under the Auspices of the National Committee on Maternal Health. Edited by Earl T. Engle. Cloth. Price, $3.75. Pp. 251, with illustrations. Princeton University Press, Princeton, New Jersey; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

This book comprises sixteen papers read at the conference of the National Committee on Maternal Health, held in February 1946. Much valuable material is contained in them. Although some papers are mainly of practical importance for the veterinarian and animal breeder, they are of great interest to the progressive physician. For the gynecologist there is much of interest concerning the changes of the ovary at the time of ovulation, the biology of human and animal spermatozoa and their viability and behavior in the cervix and the other parts of the female genitalia. Artificial insemination and the changes in the cervical mucus during the menstrual cycle are admirably discussed by experts in this as in the other fields. The impression gained from reading this book is of the great progress achieved in the last few years in knowledge of the reproductive process. This small but comprehensive book deserves to be read carefully by every biologist, veterinarian, gynecologist and urologist.

The Engrammes of Psychiatry. By J. M. Nielsen, B.S., M.D., F.A.C.P., Associate Clinical Professor of Neurology and Psychiatry, School of Medicine, University of Southern California, Los Angeles, and George N. Thompson, A.B., M.D., Assistant Clinical Professor of Neurology and Psychiatry, School of Medicine, University of Southern California, Los Angeles. Fabrikoid. Price, $6.75. Pp. 509, with 28 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1947.

The dust jacket of this volume states that the system of biologic psychiatry elucidated within removes all the mysticism of psychiatry which has puzzled physicians in other branches of medicine. This is fine except for the fact that one fears that the psychiatrists themselves will become puzzled on considering many of the concepts postulated in the book. The jacket indicates that "the validities set forth will enable physicians and students to now move in an orderly manner, accurately, and with confidence in this comparatively new field." In the preface the authors indicate their approach by stating that they believe that anatomy and physiology of the brain offer the only true basis for an understanding of mental disturbances! They aim to present in this book the anatomy and physiology of human behavior.

After an introduction, the writers proceed to a discussion of conation, which, they conclude, depends on a motor mechanism made up of "three hierarchies of cerebral structure—the basal one being the periaqueductal gray matter; the thalamic, the ventrolateral nucleus; and the cortical, the rolandic area."

The chapters which follow consider such subjects as consciousness, awareness, attention, the instincts, the emotions, the will and personality. Regarding the instincts, the authors state (page 40) that "the instincts which are present at birth have their neuronal patterns in the diencephalon. Those which require knowledge must await cerebral myelination before they can express themselves; those which require gonadal development must await puberty." On the same page it is stated that the instincts "are the source of all purpose and desire; hence they are the foundation of behavior. Intellect may modify and inhibit instinctive drives but rarely does it set aside the force of an instinct."

It is admitted that quoting out of context may sometimes be unfair; nevertheless it is believed that the following quotations should be considered. In a consideration of free will and determinism (page 48) the authors note in discussing premeditation, and so forth: "As there must be a final appeal, there is no appeal from the ruling of the supreme court. Our rulings in this country by a vote of 5 to 4 in the highest court are mute evidence that the best judgments are differently motivated—the best judges do not have a completely free will." It is difficult to see how court decisions based on an interpretation of the law can become involved in a discussion of free will.

Proceeding through a discussion of some definite mechanism of the mind, the authors discuss the psychoneuroses. They find the dynamic criterion, largely developed by the freudian school, to be of value, and note that the dynamics cannot always be found. They state that "the ability to find them depends largely upon the skill of the person doing the searching. Just as the 'silent areas' of the brain are silent only to those who do not understand their language, so are the psychoneurotic mental mechanisms hidden from the person unaware of their influence on cerebral physiology."

In their discussion of the psychopathic personality, the writers find that the location of cerebral trauma resulting in psychopathy is important but difficult to establish. They discuss cerebral lesions and end by saying: "Nevertheless much clinical experience points to frontal lobe lesions as causes of psychopathic behavior."

In the discussion of schizophrenia it is noted that the early symptoms are apathy or emotional poverty, retraction from environment and so forth. As these indicate to the authors a disorganization within the diencephalon, they state that "we believe that the basic pathology is an engrammatic diencephalic disorganization."

Manic depressive psychosis, involutional disorders and the syphilitic psychoses come in for rather complete consideration. On page 288 one notes that in discussing involutional disorders the authors state that "The pathological physiology is apparently a partial diencephalic disorganization along with endocrinous.

involution. The latter reflects in turn on the diencephalic function with consequent depression of function."

There are numerous other quotations which one might utilize to indicate that this mechanistic-anatomic approach misses the point throughout. Very few psychiatrists will concur in the hypotheses expounded or the conclusions drawn, and the book is not recommended.

Entstehung und Früherfassung des Portiokarzinoms: Weitere Erfahrungen mit der systematischen Kolposkopie an der Zürcher Frauenklinik, zugleich ein Beitrag zur Frage der Krebsentstehung. Von Hansjakob Wespi, Chefarzt der geburtshilflichgynäkologischen Abteilung am Krankenhaus Frauenfeld, ehemals I. Oberarzt der Universitäts-Frauenklinik Zürich. Cloth. Price, 18 Swiss francs. Pp. 183, with 94 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel 10, 1946.

Wespi has made a study by conventional histologic methods of the epithelium of the uterine cervix with special reference to cell types which may be considered precancerous. He concludes that adult, fully differentiated epithelium does not give rise to neoplastic cells, but rather that the change antecedent to cancer is in the germinal layer. Evidence is advanced that atypical cells, indistinguishable from precancerous ones, are associated with injury, inflammation and endocrine imbalance, although quantitative measurements of the imbalance are not specified. Emphasis is given to the long period of latency which may exist before a precancerous area develops the power of unrestrained growth. This is, of course, quite in accord with the observation of other groups. The author makes special reference to the multicentric origin of cancer of the cervix. He advances the theory that multiple origin is evidence against the origin of cancer by the mutation of normal cells and in favor of the virus theory. This volume can be recommended to all those interested in cervix cancer as a scholarly treatise of a conventional type.

Fatigue and Impairment in Man. By S. Howard Bartley, Ph.D., Professor of Research in the Visual Sciences, Dartmouth Eye Institute. Dartmouth Medical School, Hanover, N. H., and Eloise Chute, M.A., Research Associate in the Visual Sciences, Dartmouth Eye Institute, Dartmouth Medical School. Foreword by A. C. Ivy, Ph.D., M.D., Vice President, Chicago Professional Colleges, University of Illinois, Chicago. Cloth. Price, $5.50. Pp. 429, with 60 illustrations. McGraw-Hill Book Co., Inc., 330 W. 42d St., New York 18, 1947.

This is a thoughtful and well written introduction to an important and difficult subject. The factors which limit human work productivity and endurance are numerous and complex. Besides such obvious things as physical defects and frank disease states, there are large intraindividual and interindividual differences which reflect innate peculiarities, the immediate environment in all its complexity and the physiologic and psychologic states. The scope of the subject makes it necessary to survey a great variety of facts which are presumably basic to the synthesis which is called human behavior. The result is in part a sort of combination textbook of physiology and psychology with inferences as to application to fatigue. The expert may be impatient with the repetition of familiar facts and may disagree on emphasis. The tyro may often find himself beyond his depth and may wish for more didactic statements of "do's and don'ts." But the book should have much value to the intermediate class —physicians, plant engineers, sociologists, personnel managers and the like. It might have been better if the book could have been delayed a year or two. A great deal of important research from the war period and immediately after is not represented; the references to the literature, such as those on the effects of hot environments and on metabolism and nutrition, are already somewhat out of date in some areas.

Venereal Diseases in General Practice. By Svend Lomholt, M.D., O.B.E., Prof. of Clinical Dermatology, Copenhagen. With a supplement on Penicillin, Mapharside, Sulphathiazole, etc. Fabrikoid. Price, 25s. Pp. 233, with 117 illustrations. London: H. K. Lewis & Co., Ltd., 1946.

This is an English edition of the Danish textbook which has been used widely throughout the Scandinavian countries. Delayed in publication because of the German occupation of Denmark, the book now is out of date, not so much in the clinical aspects of syphilis as in respect to the discussions on therapy. The clinical manifestations of early syphilis are well covered and beautifully illustrated; the late manifestations of the disease, aside from the benign late lesions of the skin, are conspicuously slighted.

Synopsis of Allergy. By Harry L. Alexander A.B., M.D., Professor of Clinical Medicine, Washington University School of Medicine, St. Louis. Second edition. Fabrikoid. Price, $3.50. Pp. 255, with 22 illustrations. The C V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This new edition presents the essentials of allergy in a compact form and includes consideration of topics which have arisen since the first edition was published. These include the so-called antihistaminic drugs, work in vascular allergy, the relation of allergy to infectious diseases and sensitization to drugs and chemicals. These newer subjects are well handled. The section on bronchial asthma remains the best part of the book and is much better covered than any other section. There is an appendix which contains miscellaneous information, e. g., preparation and standardization of extracts, some sources of allergens, description of various methods of testing, elimination diets and tables concerning ragweed distribution and causes of contact dermatitis. The reader is given a bird's eye view of the subject of allergy, but for more detailed instructions regarding particular phases of allergy he must consult larger books or medical articles, a few of which are noted in this volume.

Drawbacks exist. The statement that "the skin test which was looked upon as absolute is now regarded as unreliable" *(page 17) implies that skin tests are futile and a waste of time.* Nothing is further from the truth, and the author undoubtedly did not mean to imply that skin tests are without value. Every worker in the field know that skin tests, properly done and properly interpreted, represent a great advance in the detection of causes of allergic symptoms; they rank close behind the careful history, examination and clinical trial, and in some cases they actually take precedence. The author, too, has apparently completely accepted the theory that contact between a specific antibody "and the atopen causes the release of histamine (H-substance)." This theory may be correct but has not been proved. The list of materials used for skin testing is fairly complete but should certainly include more molds, karaya gum and May flies. The author states that "frequently only some thirty common atopens are used for routine testing." There is no doubt that when one limits his testing to so few a number he will miss some important reactions. The more different materials used for testing the more the chance of finding something which will lessen the number of so-called "nonsensitive" or "intrinsic" cases. Surgery of the nose and nasal sinuses is advocated a little more strongly in intractable patients than by most allergists. The swing recently is distinctly away from nasal surgery except for purulent conditions, severe obstruction and large mucous polyps. Most allergists do not agree that "specific pollen therapy (for hay fever from tree pollen), as a rule, is not indicated" (p. 118). The section on the various allergic conditions of the eyelids is meager. The section on allergic dermatoses is excellent; allergy to nail polish is frequent and should be included (p. 180). The use of tetanus and diphtheria toxoids should be discussed under "serum allergy." Despite these few shortcomings the book is valuable for medical students and for the doctor who wants information in concise form.

Illustrations of Anatomy for Nurses.. By E. B. Jamieson, M.D. Looseleaf. Second edition. Paper. Price, $3. Pp. 72, with 64 plates. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

This handbook for nurses includes a selection of plates from the author's larger work "Illustrations of Regional Anatomy." It is printed on heavy plate paper and spirally bound to open out flat. Although a few slight modifications have been made in the color printing, the full page plates are the same as in the larger work from which they are taken. The book, which is really a hand atlas, is intended for nurses undergoing instruction in anatomy and as a supplement to whatever textbook is used. The plates are unusually clear owing to their somewhat diagrammatic character and to the extensive use of color to differentiate structures and parts. In fact, one could wish that slightly less color had been used or at least that it had been more restrained. Despite the somewhat violent color, the illustrations are skilfully designed and possess a high teaching value. Labeling occasionally departs from commonly used American terminology but is on the whole clear and complete. Nurses will find this striking little volume a valuable quick reference and a worthy addition to their library.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

IMMUNOLOGIC TESTS IN UNDULANT FEVER

To the Editor:—What is the percentage of positive agglutination tests and positive intradermal brucellin tests in proved cases of undulant fever. Also, is there an overlapping of positive tests in these cases?

M.D., Pennsylvania.

Answer.—Owing to uncontrollable variability in the disease itself and in laboratory diagnostic methods, the question cannot be answered satisfactorily by a simple citation of published data without considerable qualification.

Lack of a standard antigen for the agglutination test and a standardized technic for its performance introduces errors of considerable size in the determination of the frequency of positive reactions in proved cases of brucellosis. For this reason alone the data in published series are variable. Serums from certain culturally proved infections, estimated from 4 to 10 per cent in acute brucellosis, will fail to agglutinate many different strains, even the one recovered by culture. The agglutination test is more frequently positive in acute than in proved chronic brucellosis. Complete agreement is absent concerning the agglutinin titer level at which significance, or positivity, begins and from below which this is absent.

With these limitations on accuracy in mind, the cumulative totals from published figures on the frequency of "positive" agglutination tests vary from 75 to 95 per cent for acute and 5 to 50 per cent for chronic brucellosis.

With respect to "brucellergen" (brucella protein nucleate) (not brucellin) as the agent for intradermal testing, the producer states that about 5 per cent of those actively infected will not react to it, and that the majority of such persons also fail to show serum agglutinins. The cumulative results of various published experiences with this substance indicate that from 5 to 8 per cent of cases of proved brucella infection fail to react positively, and that this may or may not be correlated with absent agglutinins.

GALACTORRHEA

To the Editor:—A housewife aged 33 has had galactorrhea for the past six months. Oral atropine to the limit of tolerance has not checked it appreciably. Estrogen in oil temporarily decreased the flow following administration of 20,000 units twice weekly. When this dosage was reduced to once a week galactorrhea reappeared. This woman has suffered from a syndrome which fits exactly the functional hypoglycemia described by Conn (Conn, J. W.: The Diagnosis and Management of Spontaneous Hypoglycemia, J. A. M. A. 134: 130 [May 10] 1947). Apparently this is controlled by a high protein, low carbohydrate diet. Although her gallbladder was removed three years ago she has gaseous distress, bloating and burning sensation following the ingestion of food. These symptoms are relieved by aluminum hydroxide gel ("creamalin" N.N.R.) taken after meals. Three months ago fluoroscopic and radiographic examination of the upper part of the intestinal tract revealed no abnormality. Interesting features of the physical examination are (1) unusually short, but not tapering fingers; (2) excessive hirsutism of the forearms, legs, axillas, linea alba and areolae of the breasts and (3) blood pressure 120 systolic and 70 diastolic and 134 systolic and 90 diastolic on separate occasions. Her last of two pregnancies occurred one year ago. What causes the galactorrhea? What can be done to obtain permanent relief?

M.D., Colorado.

Answer.—Galactorrhea is rare. Stander (Stander, H. J.: Textbook of Obstetrics Designed for the Use of Students and Practitioners, New York, D. Appleton-Century Company, Inc., 1945) and DeLee and Greenhill (DeLee, J. B., and Greenhill, J. P.: Principles and Practice of Obstetrics, ed. 9, Philadelphia, W. B. Saunders Company, 1947) have stated that the condition is "intractable." Its cause has not been determined. In view of the latest information on the sources of lactation one must consider the possibility of some abnormal endocrinal function or tumor, particularly of the pituitary gland but less likely of the thyroid or the ovaries. Both authorities agree that the practical therapy of compression of breasts by tight binders is worthy of thorough trial. Greenhill suggests the use of diethylstilbestrol and androgens. Since this patient has excessive hirsutism, androgens should be avoided. If the simple measures of tight binder and breast support fail, then a thorough study of the endocrinal systems should be made. Special attention should be directed to the pituitary gland for evidence of tumor.

POSSIBLE TABES DORSALIS

To the Editor:—A man aged 61 has a negative serologic reaction to the Wassermann test, gastric and rectal crises and Charcot joint (neurogenic arthropathy) which is moderately progressive. He has no evidence of dementia paralytica. His mental and emotional condition is not affected. He has reflex rigidity of the pupils and absent knee jerks. The patient had a primary chancre at 19 years of age. He refuses to have a spinal fluid test performed. Please outline treatment. Should examination of the spinal fluid be insisted on? No accurate record of previous treatment is available.

M.D., Illinois.

Answer.—The patient described cannot be intelligently treated without examination of the spinal fluid, including a cell count, quantitative protein estimation, quantitative complement fixation test (not flocculation) and colloidal gold test. Assuming the patient's general physical condition to be satisfactory without serious complicating diseases, the best form of treatment for tabes dorsalis with gastric crises and a neurogenic arthropathy is fever therapy with induced tertian malaria infection combined with simultaneous administration of penicillin, the latter in a total dosage of 6,000,000 to 10,000,000 units. This treatment offers about a 50 per cent chance of relief from the gastric crises and some prospect that further degeneration of the affected joints may be interrupted. Six to twelve months' observation following treatment is necessary to determine its effectiveness. If ineffectual, certain further suggestions might be offered. The treatment of tabes dorsalis is a highly individualized problem. The management of the Charcot joint is largely orthopedic.

LIVER EXTRACT IN PERNICIOUS ANEMIA

To the Editor:—A patient with pernicious anemia, 72 years of age, has complete loss of vibratory perception, as tested with a tuning fork and loss of proprioceptive sense in the lower extremities. She was not receiving liver therapy at the onset of these symptoms. Is there hope of producing sufficient improvement to enable the patient to walk again? Would 30 units of liver extract weekly constitute an adequate dosage? How long after initiation of treatment could one expect improvement?

Clifford W. Atherton, M.D., Fairview, Ill.

Answer.—Patients with pernicious anemia, bedridden because of neural involvement, often show striking improvement with liver therapy. Not uncommonly such patients walk again and carry on their usual activities. The neurologic response, which is not always predictable, will depend on the duration and degree of involvement. Thirty units of liver extract weekly should be adequate during the early months of treatment. Later, this dose can be given every two to three weeks.

Improvement in cord symptoms and signs may be noted within a few weeks but may not become apparent for six months or longer.

PROSTHESIS FOR NASAL CANCER

To the Editor:—A patient who will require a plastic prosthesis following radical extirpation of an extensive basal cell cancer of the nose refuses operation unless I can arrange for a prosthesis. Where can this be obtained. She has received roentgen therapy from other physicians without permanent improvement.

M.D., Ohio.

Answer.—A plastic prosthesis is made from an impression of the nose using plaster of paris. If extensive operation is contemplated it is not worth while to take the impression in advance since the contour of the adjacent cheek and lip might change from postoperative contraction of the scar. The impression should not be taken until healing is complete, possibly six to twelve months postoperatively.

Properly constructed and hand tinted, a prosthesis will resemble the normal nose at close inspection. The ready-made papier-mâché type may be employed temporarily to cover the operative field while healing occurs. These are probably not more conspicuous than an adhesive dressing. Such a prosthesis may still be obtainable at one of the regular instrument houses.

IMMUNIZATION FOR TROPICS

To the Editor:—Occasionally during the fall or winter patients go to Mexico for a vacation. What immunizations are advisable before they make this trip?

M.D., Colorado.

Answer.—Vaccination against smallpox and also for the prevention of typhoid are the most important. Recently it has been reported that evidence of a successful vaccination against smallpox is necessary before entry to Mexico is permitted.

Malaria is another disease which should receive consideration; therefore it might be well to take prophylactic doses of quinine or quinacrine, if the locality which is to be visited is known to be a malarial district.

PARALYSIS FOLLOWING CEREBRAL HEMORRHAGE

To the Editor:—The blood pressure of a woman patient aged 56 is 155 systolic and 90 diastolic; previously it was 190 systolic. She had paralysis of the eye on the same side as paralysis of her legs and arms. She can now move the arm and can walk, but there remains a partial deadening of sensation, with weakness of the affected side. She can tell when the affected side is touched, but the sense of incomplete feeling is annoying. Is there any treatment?

R. W. Hartwell, M.D., Beaumont, Calif.

ANSWER.—Although the history is insufficient to make an exact diagnosis, there is presumptive evidence that this patient had a cerebral thrombosis in the internal capsule and adjacent areas of her brain on the side opposite to the paralysis. The weakness is due to partial interference with the motor pathways, and her complaint of disturbed sensation probably indicates that the thalamus was also affected. The thalamus is the central site of sensation in the brain and acts as a substation for sensory impulses on their way from the periphery to the cortex. The thalamic syndrome is often accompanied by severer symptoms than those described. Having partial deadening of sensation is a minor annoyance when compared with intense paresthesia or loss of position sense. If the initial onset occurred more than three or four months prior to the description of her symptoms, it is unlikely that further recovery will take place and no known form of medication will modify the course of the disease favorably. Occasionally, phenobarbital given in doses of 15 mg. (¼ grain) aids in stabilizing abnormal sensations during the early period of convalescence.

USE OF PERTUSSIS VACCINE

To the Editor:—1. Has a young unimmunized patient recently exposed to pertussis any chance to avoid the disease? 2. Will pertussis vaccine minimize symptoms of the disease once early symptoms have developed? 3. After whoop develops? 4. In a child who has completed a standard pertussis immunization one month to several years prior to exposure, would (treatment with pertussis vaccine) (*a*) before any cough, (*b*) after coughing but before whooping or (*c*) after whooping has begun have any value?

M.D., Iowa.

ANSWER.—Under the circumstances outlined in question 1, it is doubtful that any preparation injected into the exposed susceptible subject will produce *active* immunity rapidly enough to prevent an attack.

The answer is definitely "no" to questions 2 and 3. A much more rational procedure would be to give a dose of hyperimmune lyophiled human serum, such as that prepared by the Philadelphia Serum Exchange. If exposure is repeated, a second injection of this human serum can safely be given ten days to two weeks later. This *passive* immunity gives fairly good protection for two or three weeks. It should, of course, be followed by active immunization by vaccine of the Sauer type, either plain or combined with diphtheria toxoid in the alum-precipitated preparation.

In answer to question 4, a booster injection of pertussis vaccine in a child immunized some years previously is of definite value if given prior to the development of any symptoms. If given after any cough has begun, its value is questionable.

HORMONES AND MAMMARY HYPOPLASIA

To the Editor:—What information is available concerning the value of estrogenic hormone in ointment for mammary hypoplasia, used externally over the glands? Please give the names of several commercial products that have proved useful in this condition.

Cyrus H. Stoner, M.D., Atlanta, Ga.

ANSWER.—Estrogens are absorbed through the skin from ointments applied topically, but their use as described is not acceptable. This method of administration is wasteful.

The action of hormones absorbed through the skin is a complex one and has effects throughout the body.

Estrogens applied topically to the breasts may produce hyperpigmentation of the nipples and aereolae. This effect may follow estrogenic therapy by other routes as well (Davis, M. E.; Boynton, M. W.; Ferguson, J. H., and Rothman, S.: Studies on Pigmentation of Endocrine Origin, *J. Clin. Endocrinol.* **5**:138-146 [March] 1945).

At present there is no more justification for the use of hormonal therapy for the specific purpose of developing hypoplastic breasts than for similar attempts specifically to influence body height or weight or the size of the genitals.

The complex effects of hormones must always be kept in mind, and in contemplating their use the body must be thought of in terms of the whole rather than in terms of an organ or part.

SECONDARY ANEMIA FROM WELDING FUMES

To the Editor:—Do welding fumes from galvanized iron, stainless steel, copper, nickel and black iron if inhaled cause mild secondary anemias?

Raymond J. Millemann, Long Island, N. Y.

ANSWER.—Exposure to the substances mentioned does not favor the occurrence of secondary anemia. On occasion, lead may be present in traces as an unknown accidental constituent particularly if the metals are reclaimed lots. Under this circumstance, sufficient intake might cause an anemia from lead poisoning. If arc welding is involved and if coated welding rods are employed, coating components may induce anemia. If carbon monoxide is generated, which is unlikely, long exposure may produce a polycythemia. Notwithstanding all that precedes, this type of work under unfavorable conditions is sometimes associated with impairment of health for which diagnosis is difficult. Metal fumes, and notably the fumes of zinc, act as incentives to alcoholism and may produce a distaste for food. A mild secondary anemia may appear without specific occupational cause.

PREVENTION OF MOLD GROWTH ON BOOKS

To the Editor:—The Journal of Nov. 9, 1946 contains a query and answer concerning the removal of must odor from books. The reply states that there is no satisfactory way of inhibiting mold growth in a humid atmosphere. At the request of the Book Collectors' Society of Australia, S. L. Larnach and I published a paper on this subject in the *Laboratory Journal of Australia* in August 1945. Many experiments have shown that there is no growth of fungi when the relative humidity is below 75 per cent. It was therefore decided to investigate the problem of maintaining the humidity within a bookcase below 75 per cent, either continuously or during very humid weeks. As a result of our studies it was recommended that two fairly open meshed bags containing a half pound of silica gel be hung on each book shelf during periods of high humidity. When not in use the silica gel should be kept in an airtight container. After the gel is spent, it can be reactivated by heating it for some time in order to drive out the water vapor.

B. D. Wyke, M.B.B.S., Sydney, Australia.

Research Fellow in Neurology and Neurological Surgery, University of Sydney.

[The *Bulletin of the U. S. Army Medical Department*, May 1945, page 28, published the following item on this subject, which was reprinted from *Science* of March 2, 1945: In warm climates following a long rainy spell, book bindings frequently support a heavy growth of mold, which, if unchecked, will disfigure the books. While mere dusting removes the superficial growth, it does not disturb the mold growing in the paste of the bindings. Several years ago, following a wet season, the Duke Hospital Library had an epidemic of mold in bound journals which stood near an underground ventilator drawing air from an open areaway. Duncan C. Hetherington of the Department of Anatomy, Duke University School of Medicine, was called on for suggestions to remedy the situation. The vent was closed and the following solution was wiped over the molded bindings: thymol crystals 10 Gm., mercury bichloride 4 Gm., ether 200 cc., benzene 400 cc.

The treated volumes have never since shown any tendency to mold, and any other outbreaks of mold have been similarly and effectively treated. The solution is poisonous and inflammable and should be used carefully in an open room or outdoors with no source of fire nearby. It is best applied with a cotton sponge tied to a suitable applicator or held by forceps, so that none of it gets on the fingers. The solution penetrates the bindings readily and dries rapidly, leaving no precipitate. One application is usually sufficient, and the books may be returned at once to their places. It is wise to test first one corner of the bindings before using the solution, to discover whether the dye will run or change in any way. In our experience it has not altered the appearance of the goods nor affected the letter stampings. The solution may also be safely used on record album backs, leather boxes and luggage, but it should never be used on any wearing apparel.]—*Ed.*

PUBLIC HEALTH

To the Editor:—Several physicians have asked me to write objection to the definition of "public health" which appears in an answer to Dr. Gleeten's query about state medicine on page 544 of The Journal of Oct. 25, 1947, and which reads as follows:

> "Public health is a form of socialized medicine concerned with special groups and special activities for the protection of the health of the people as a whole."

All of us engaged in teaching the sciences of preventive medicine and their application through tax-supported services resent the inclusion of public health as a form of socialized medicine. It is no more socialized medicine than the public school is socialized education, or the police or fire department of a city a socialized activity.

Public health services consist of the application of the sciences of preventive medicine through government or with its authorization for social or community ends or benefit. Public health departments, local and state, are integral parts of government, based on the democratic organization of society by majority rule through the power of the suffrage and authority to appropriate tax moneys. This is not socialization of medicine nor should it be referred to as a form of socialized medicine.

Please take my gentle objection to heart and do not permit any one to put the label of socialized medicine on public health through the pages of The Journal.

Haven Emerson, M.D., New York.

NOTE.—"Public health" is, of course, "social" medicine.—ED.

EMERGENCY TREATMENT OF APOPLEXY

N. C. GILBERT, M.D.,
and
GEZA de TAKATS, M.D.
Chicago

Acute occlusions occurring in the peripheral vascular tree produce neurovascular phenomena which have been successfully treated for several years in our clinic by administration of antispasmodic drugs, by block of the corresponding sympathetic ganglionated chain or by embolectomy.[1] This knowledge has not been generally applied to cerebral circulation, mainly because the nervous control of the cerebral vessels has been authoritatively questioned. While the vessels of the cerebral cortex react to mechanical, thermal, chemical and electric stimuli,[2] and while pial arteries have been seen to go into spasm on being stretched [3] or on increase of blood pressure,[4] little evidence has been forthcoming from these sources that any nervous control is clinically significant. In fact, the consensus as summarized by Forbes and Cobb in a symposium on cerebral circulation [5] stressed that cerebral circulation is remarkably stable, that fright, anger or other emotions do not change the vascular caliber, that while the existence of vasomotor nerves cannot be denied, their constrictor activity in the vessels of the pia is about one-tenth that in the skin. It has been concluded by this group of workers that the neurovascular mechanism of the brain is weak and that it is not likely to participate in any process resulting in permanent damage of nervous tissue.

The factors determining the size of cerebral vessels have been listed by Aring [6] as (1) the vasodilatation, brought about by carbon dioxide, by nitrites, by nicotinic acid, (2) changes of blood pressure, (3) local activity of a group of neurons demanding more blood for their metabolism and (4) changes in the degree to which the venocapillary bed resists blood flow, as in extremes of hydration and dehydration. Thus edema tends to narrow capillaries and vessels, whereas dehydration encourages their dilatation. Systemic arterial and intracranial venous pressures are of more importance than the aforementioned factors in the regulation of the amount of blood that normally flows to the brain.

All these factors are recognized as acting on the peripheral circulation, but it is clear that while the extremities subserve the regulation of heat and have a highly fluctuating vasomotor tonus, the cerebral vessels do not engage in this function, and many safeguards, predominantly the carotid sinus and the aortic depressor mechanisms, are developed to maintain as even a total blood flow as possible.[7]

In seeming contrast to the findings of physiologists and laboratory experimentalists, clinicians have postulated for many years the occurrence of fleeting and reversible vascular phenomena, which were difficult to explain on any but a vasomotor basis. The rapid improvement after cerebrovascular accidents or trauma of the head, the fleeting motor and sensory phenomena with complete clinical restitution, the vasoconstrictor phase of migraine followed by vasodilatation and headache have always been regarded as due to neurovascular changes. In fact, apoplexy has been regarded as an angiospastic insult.[8] Recently the form of hyperemia described by Ricker [9] and applied to the pathology of head trauma by him as early as 1919 has received confirmation and elaboration by Chase,[10] by Evans and Scheinker [11] and by Aring.[6]

Since in the mind of the clinician vasospastic phenomena usually mean simple vasoconstriction, it might be well to summarize Ricker's original conception, since it is applicable to so many fields of vascular pathology and because until quite lately he has not received the credit which he deserves. Ricker stated clearly that a spasm of contractile elements that has lasted for some time or is of unusual intensity may lead to dilatation and stasis of the venocapillary bed, with diapedesis of plasma or of cellular elements, on one hand, and to persistent constriction of the arteriolar bed, on the other. Ricker and his school examined a great many organs that were at rest and in activity by transillumination and the use of the capillary microscope. They showed that the hyperemia with stasis was not the reactive hyperemia of Bier, with vasodilatation of all terminal vascular segments and with increase of the rapidity of blood flow. The hyperemia in question, which Ricker named "peristatic," results from venocapillary dilatation with arteriolar constriction, the capillary bed being paralyzed, not responsive to direct stimuli, and the blood

leaking out of the dilated segments by diapedesis. Thus his conception was the morphologic forerunner of the classic experiments of Landis and co-workers[12] concerning the anoxic permeability of the capillaries, of the recent studies of Knisely and Block[13] of the "sludge" effects in experimental malaria and of the studies of Lange and Boyd[14] on frostbite.

Such venocapillary paralysis is certainly not uncommon in peripheral vascular disturbances and usually indicates severe terminal vascular occlusion. Diapedesis of red cells surrounding segmental areas of venous stasis is seen in the extremities as a forerunner of gangrene. Such phenomena of stasis and diapedesis occurring in the brain of the experimental animal have been recorded by Villaret and Cachera,[15] who observed the vessels of the pia through a window in the skull after embolic occlusion.

It is for the reasons cited that a short communication of Leriche and Fontaine,[16] made in 1936, aroused so little interest. These authors presented 2 cases of postoperative hemiplegia, in which an infiltration of the stellate ganglion of the affected side resulted in a striking regression of symptoms. They felt that the block influenced the zone of vasoconstriction around an ischemic or a hemorrhagic area and that the regression of edema beneficially influenced the residual symptoms. Stimulated by this report, Mackey and Scott[17] treated 19 patients for acute cerebrovascular accidents, 9 of whom derived definite benefit. They reported that cerebral hemorrhage does not respond well, particularly in the aged, that patients affected by cerebral thrombosis should fare better, depending on the amount of cerebral arteriosclerosis, and that cerebral embolism occurring in the young is the ideal case for this treatment. While, obviously, some patients with apoplexy improve spontaneously during the first few hours, they do not do this within the first few minutes. This was their criterion for a therapeutic effect of the block.

Our interest in the nervous control of the cerebral circulation stems from several sources. In doing cervical sympathectomies for retinitis pigmentosa, Gifford and one of us (G. de T.)[18] could find no definite improvement in the patients referred for operation, but immediately after the operation there was marked retinal hyperemia. Since that early report a number of other patients have been operated on by one of us (G. de T.), and when one of them was tested preoperatively with stellate block, a striking improvement in visual acuity was encountered.[19] That vascular reflexes are important in insuring adequate circulation in the brain, especially in the erect position, was observed by Capps and one of us (G. de T.).[20] Two cases were reported, in which bilateral denervation of the carotid sinus resulted in marked postural hypotension seventeen months and eight and a half months postoperatively, together with symptoms of cerebral anoxia. It seemed as if the weakening of this mechanism under anoxia precipitated loss of consciousness.

While an opportunity to view the pial vessels through the opening produced by raising a bone flap during the course of a stellate block is not likely to occur very often,[21] Villaret and Cachera,[15] in their classic set of experiments, photographed vasoconstriction of cortical vessels after experimental embolism, which could be abolished by block of the cervical sympathetic nerves. They also demonstrated late circulatory disturbances in the presence of cerebral infarction and demonstrated anastomosis of cortical vessels in and around the cerebral infarcts, disproving the concept that these are end arteries.

All the foregoing considerations led us to adopt a more active method of treating patients who had undergone cerebrovascular accidents. We propose to discuss the material studied, the technics employed and the results obtained. In this country Volpitto and Risteen[21] noted good results from a stellate block on cerebral thrombosis, but warned against its being used in the presence of hemorrhage.

MATERIAL STUDIED

One hundred and twenty-one patients were used for the basic study. Apoplexy was differentiated as cerebral hemorrhage, thrombosis and embolism, our criteria being based on the analysis of Aring and Merritt.[22] While they stated that differentiation of these lesions should be possible in nearly 100 per cent of cases, this ideal may not always be reached in a general hospital, where such patients are not all admitted to the same service and their study and treatment are not standardized. We apply our criteria for the diagnosis of the three variants of the apoplectic insult as follows:

Cerebral Embolism.—This diagnosis is made when a patient showing a sudden cerebrovascular insult has an obvious cardiac lesion for the source of the embolus, or has had previous embolic episodes involving the brain or other part of the body, and has clear spinal fluid with no elevation of pressure. The age of the patient is usually lower than that of a patient affected by thrombosis or by hemorrhage, because in many instances the embolus originates from a rheumatic heart. Nevertheless, this is somewhat offset by the fact that there is a group of patients who show emboli from myocardial infarcts[6] or from sclerotic plaques or aneurysms. This is also true of the blood pressure readings, which are said to be the lowest in this of all three forms, but there is no reason why hypertensive cardiovascular disease could not be complicated by cerebral embolism. Also, the blood pressure recorded in the history may reflect a state of peripheral failure, a response to intracerebral hemorrhage or a reactive pressor response to increased intracranial pressure. For this reason, the help obtained from the patient's age and blood pressure in differentiating the various forms of apoplexy should not be valued too highly. In the group of 15 patients classified as suffering from cerebral embolism the ages varied from 18 to 60, the average age being 53 years. Their blood pressure (measured in millimeters of mercury) fluctuated between 110 systolic and 80 diastolic and 210 systolic and 106 diastolic, with an average of 143 systolic and 85 diastolic. Their spinal fluid was clear;

the pressure was normal. Seven patients belonged to the hypertensive-arteriosclerotic group and 8 to the rheumatic group (table 1).

In peripheral arterial embolism, the chances for a survival of the limb, with or without embolectomy, are better in the rheumatic group. Such a situation seems to exist here because, of the 6 patients who had cerebral embolism based on rheumatic heart disease, only 1 died, a 40 year old man with heart failure; whereas, of the remaining 9 who had cerebral embolism with postcoronary complications and hypertensive cardiovascular disease, 5 died, and while this has no statistical significance in such a small series, it is obvious that the prognosis as to life would be better in the rheumatic group.

Cerebral Thrombosis.—A more appropriate designation for this condition would be cerebral softening, since, as Aring[9] pointed out, the postmortem examination reveals, apart from stenosis and hyalinization of arterioles, areas of malacia or necrosis, but seldom actual thrombosis. In this group of 53 patients, 9 died in the attack, and on 4 of these autopsy was performed. Of the 4, only 1 had thrombosis of the middle cerebral artery. One died of coronary thrombosis with pulmonary embolism and many scattered areas of softening; another had stenosis of the middle cerebral artery with malacia of the striate bodies and of the white matter of the right hemisphere, and still another died of coronary thrombosis and terminal bronchopneumonia. In these patients as well as in the others who died, in whose cases autopsy observations are not available, a fall in blood pressure and the anoxia of the inevitable bronchopneumonia of the unconscious patient seem to transform the silent or latent cerebral softening into the clinical entity of "thrombosis" or even into death.

To make a diagnosis of encephalomalacia—not embolism and not hemorrhage—one postulates a patient afflicted with cardiovascular-renal disease, moderate hypertension and an onset which is gradual and does not deepen. While loss of consciousness is present in approximately one half of the cases, it does not persist for many days. Increased intracranial pressure is not observed, the spinal fluid is clear, and if the pressure is elevated, this is part of the hypertensive encephalopathy; papilledema and engorgement of retinal veins are absent. The condition presented by this large group is really diagnosed, then, by eliminating embolism and hemorrhage from the causes of the stroke. The average age of this group was 60.8 years; a study of the patients below 50 years of age indicates that, of the 11 in this group, 2 died, one a 42 year old woman, with severe diabetes and hypertension, and another a 48 year old man with a blood pressure of only 120 mm. of mercury systolic and 70 diastolic. This pressure was undoubtedly a pressure in collapse. The figure for the average blood pressure of this group need not be emphasized too much, since a study of the charts reveals that the component values were determined at various stages of the attack and therefore seem meaningless. It is interesting to note, however, that the postoperative or the postcoronary hemiplegias observed were accompanied by a prolonged and rapid fall in pressure, and so were those occurring during sleep.

The onset was noted to be sudden in 25 and gradual in 28 patients; if the patient did not die of the attack or of complicating bronchopneumonia, recovery was slow, improvement being noted in 20 and no improvement in another 20 patients. Fatalities were recorded as occurring in 13 patients (24.5 per cent), all of them dying within the period extending fom the fifth to the twenty-eighth day, none earlier. The spinal fluid was clear, and only 2 patients showed a pressure of more than 200 mm. of water (table 1).

Cerebral Hemorrhage.—This form of apoplexy was diagnosed in 53 patients, 41 of whom died within the next few hours or days—a mortality of 77 per cent. The average age of this group was 58.9 years, with individual variations from 41 to 80 years. There were 33 men and 20 women. The average blood pressure was 213 mm. of mercury systolic and 120 diastolic, with extremes of 300 systolic and 120 diastolic and 120 systolic and 70 diastolic. Again one must emphasize the point that the vascular insult itself may modify the blood pressure readings, but the tendency for the highest pressure among the three varieties of apoplexies to occur in cases of hemorrhage is well enough defined. Only in a few patients was the onset gradual, but even in these deepening coma was observed. The number exhibiting a sudden fulminating onset was 49 of 53 (92 per cent). The spinal fluid was clear, with normal pressure in 30 per cent of the cases, but unfortunately spinal puncture was done in only one third of the cases in this series. Of the patients whose spinal fluid was examined, over two thirds had bloody spinal fluid and three fourths had bloody spinal fluid or spinal fluid under increased pressure (over 160 mm. of water). In massive hemorrhage, the outlook for improvement was poor, and only 9 per cent showed improvement; 14 per cent were unimproved and 77 per cent (41 patients) died. Only in 16 cases was permission to perform autopsy obtained. In our hospital, in which the rate of permission has averaged 75 per cent in the last few years, this low percentage is probably due to the difficulties in obtaining permits in cases in which the patient arrives in a comatose, moribund state and dies within a few hours. Certainly in the cases in which permission has been obtained, valuable information has been collected regarding the possibility of more active treatment of patients with acute massive cerebral hemorrhage, as well as the high incidence of pneumonic complications in the patients who survive the first few days (table 1).

From a diagnostic standpoint, the sudden onset, the stiff neck, the high white blood cell count, the bloody spinal fluid under increased pressure and the deepening coma are all suggestive of hemorrhage.

Patients unimproved....	3 (20%)	20 (38%)	
Patients who died.......	6 (40%)	13 (24%)	

A summary of the observations made on 121 patients with apoplexy admitted to St. Luke's Hospital between the years 1940 and 1946 is given in table 2. We have compiled this summary to give us a base to start from and to see whether more active therapy could not be instituted with benefit.

THE USE OF CERVICAL SYMPATHETIC BLOCK IN APOPLEXY

During the course of the past few years we have made fifty-seven cervical sympathetic blocks in 25 patients not included in the first two tables. Most patients received only one injection, but 5 patients had three, 3 patients five and 2 patients six injections during the course of their convalescence (table 3). Our indications have gradually crystallized with increasing experience. It became obvious, as already emphasized previously,[21] that cerebral hemorrhage offers little chance of improvement. In the group of 25 patients, 3 were considered to have cerebral hemorrhage; in 2 instances the diagnosis was verified by autopsy, and in the third the condition was diagnosed as being such because of the sudden onset, the stiff neck, the bloody spinal fluid and the increased spinal fluid pressure. In this case the 75 year old patient died on the third day of admission with deepening coma and vomiting. Permission to perform autopsy was not obtained. However, immediately after induction of the block, active motion of the right arm returned and speech improved, the improvement lasting for four hours. The other 2 patients showed no change in their status after induction of block and died.

TABLE 2.—*Summary of Data on One Hundred and Twenty-One Patients Treated for Apoplexies*

Diagnosis	Patients	Average Blood Pressure, Mm. Hg	Sudden Onset, per Cent	Normal Spinal Fluid, per Cent	Improvement, per Cent	Mortality, per Cent
Embolism........	15	143/ 85	100	100	40	40
Hemorrhage......	53	213/120	92	30	9	77
Thrombosis (cerebral softening)...	53	166/ 97	47	90*	38	24

* The spinal fluid contained no blood but was under increased pressure, due to hypertension.

TABLE 3.—*Patients Treated for Apoplexies by Induction of Cervical Sympathetic Block*

Patient	Injections *
15................................	15 (1)
5................................	15 (3)
3................................	15 (5)
2................................	12 (6)
25................................	57

* The figures in parentheses indicate the number of injections received by the individual patient.

Of the 12 patients in whom cerebral thrombosis or softening was diagnosed, 3 died, one on the seventeenth day, of pneumonia, one on the twelfth day, of pneumonia, one on the fifth day, of coronary thrombosis. Improvement after induction of stellate block was noted in 8 patients of this group and the criteria of improvement will be listed presently. One patient showed no improvement.

Of 10 patients considered as having cerebral embolism, immediate improvement was noted in all, but this did not necessarily alter the course of their disease; one patient of this group died on the fifth day, at which time the right internal carotid and middle cerebral arteries were found to be occluded, and the occlusion had produced a large infarct in the right cerebral hemisphere; the origin of the embolus was in the right auricle.

TABLE 4.—*The Efficacy of Stellate Block as Used to Alleviate Apoplexies*

Diagnosis	Cases	Good Responses	Poor Results
Hemorrhage..................	3	1	Death in 3
Thrombosis..................	12	8	No improvement in 1 Death in 3
Embolism..................	10	10	Death in 1
Total..................	25	19	Death in 7 No improvement in 1

Speech regained..................	5
Speech improved..................	10
Motor improvement..................	8
Flaccid paralysis abolished..................	5
No improvement..................	7

* Improvement must appear within ten minutes after the production of Horner's syndrome. Injections were done as soon as possible after admission.

It would seem, then, from the survey of this small group of cases, that embolism responds the best, thrombosis less well and hemorrhage the least (table 4). It became necessary to establish criteria of improvement, for which the house staff was instructed to look. Since spontaneous improvement is frequent, one can attribute any effect to the block only if it coincides with, or follows within five to ten minutes after, the appearance of Horner's syndrome. The criteria are listed in table 5. With few exceptions, the injections were made within the first few hours of the cardiovascular accident. In only 3 patients was the block of the stellate ganglion carried out several days or weeks later. In 1 patient, in whom an intermittent dysarthria resulted from apoplexy, a block was done to see whether the temporary improvement and deterioration of speech would not be influenced by sympathetic paralysis. This patient obtained no help. However, 2 other patients, both with paralysis of the third nerve, showed definite improvement of ocular muscle function when injections were done several days after the vascular accident.

The duration of improvement varied from a few hours to several days. Two patients died later in spite of showing a favorable response immediately after the injection. In patients who showed regression after temporary improvement, repeated injections were done; subsequent injections, however, produced hardly as marked improvement as the first one.

The most significant finding was the conversion of flaccid into spastic paralysis, since it offers proof that in the human brain affected by occlusion of a blood vessel the state of cerebral shock, "diaschisis," can be shortened so as to give way to a focal upper neuron lesion. The mechanism of cerebral shock is not clear, and hence the nature of its release is also only speculative. Obviously, any method which is capable of reducing the edema due to stasis, or improving the blood flow in parts of the brain not directly affected by the vascular insult should bring about better restitution and lessen the permanent cerebral damage.

AN OUTLINE OF THE TREATMENT

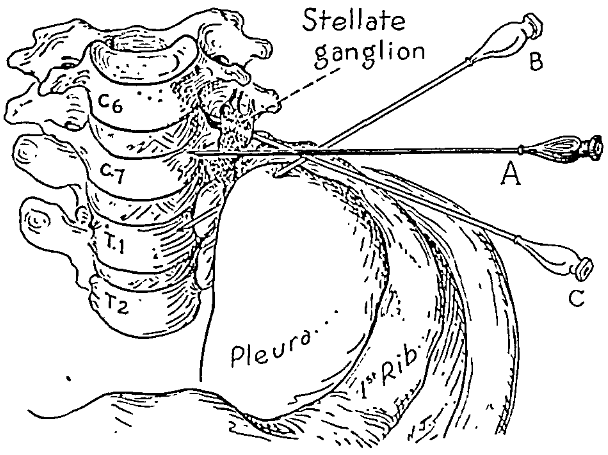
The earlier treatment can begin, the better are the chances for hastening the phase of restitution. The patient is given a brief cardiovascular and neurologic examination. The history is obtained from the relatives. The patient is immediately placed in an oxygen tent; this not only diminishes the anoxia but may indirectly aid the aortic depressor and carotid sinus reflexes. If signs of increased cerebrospinal pressure are dominant, a spinal tap is done and the spinal pressure measured. Frank blood speaks for cerebral or for subarachnoid hemorrhage, and block of the cervical sympathetic chain is not performed. Marked hypertension with signs of increased venous pressure in the neck requires venesection, which is done slowly, and not more than 300 cc. of blood is removed at one time. Unless coma is deepening and a terminal condition is obvious, and if massive hemorrhage can be reasonably excluded, a sympathetic block is performed, with the patient in bed, in the reclining or semisitting position.

For diagnostic and therapeutic purposes we have generally preferred the anterior approach to the sympathetic chain. The method used is as follows:

> The patient's neck is slightly hyperextended by a small pillow placed under the shoulder blade of the side of injection; the head is turned away from the site of injection. With an applicator dipped in a solution of iodine, a line is drawn from the mastoid process to the clavicle through the tips of the palpable transverse processes. By injection of a 1 per cent solution of *procaine hydrochloride* (without epinephrine) a dermal wheal is place over the tip of the seventh transverse process; then a 4 inch (9 cm.) 22 gage needle is inserted through this wheal. It must shortly make contact with the tip of the transverse process, which is quite superficial. Then the needle slides along the superior border of the transverse process until it contacts the body of the sixth cervical vertebra. Aspiration is now made for air bubbles, for blood, for spinal fluid, and if none of these is observed, 10 cc. of a 1 per cent solution of procaine hydrochloride is injected, aspirations being made repeatedly during this procedure.
>
> A successful block is followed within ten to fifteen minutes by Horner's syndrome, by dilatation of the conjunctival vessels, by dryness and increased warmth of the face and ear lobes of the side of injection and by rising temperature and dryness of the corresponding upper extremity.

This description represents an insignificant modification of Leriche's method.[23] The modification has been designed to make the method comparatively safe and simple in the hands of residents. There is no question that Leriche's original method and that of de Bakey and Ochsner[24] deposit the local anesthetic much closer to the stellate ganglion, and their approach is more accurate in experienced hands. In the hands of the occasional operator, doing a few blocks each month, the foregoing modification is safer, since it cannot possibly result in pneumothorax. That intravascular injections must be avoided is obvious; intraspinal injections can occur, and we know of two deaths due to this complication. Such an injection happens when the tip of the needle enters a subarachnoid projection along the cervical nerve root, even though the needle has not entered the intervetebral foramen. Since in our experience with residents, pneumothorax or actual massive collapse of the lung has occurred, we placed the injection one segment higher without influencing the efficiency of the block (figure). It must be emphasized that if the diagnostic or therapeutic block is made in cases of angina pectoris or of causalgic states of the upper extremities, a dorsal approach to the upper second to fourth sympathetic ganglions must be used. For our present purpose—in the hemiplegic patient—the cervical approach at the sixth to seventh cervical level is satisfactory.

If Horner's syndrome does not develop, the injection must be regarded as faulty and should be repeated. The injection is to be done on the side of the lesion, and the side is not immediately obvious when the patient is seen early; the patient may be quadriplegic or may have flaccid paralysis, but either a facial involvement or a beginning sensory change may point to the side of involvement. Dilatation of the pupil is more frequent on the contralateral side. Loss of pupillary reaction is more frequent in cases of hemorrhage.



Injecting the stellate ganglion by an anterior approach: *A*: Correct position of the needle, locating the lateral surface of the seventh cervical vertebra or the disk between the sixth and seventh vertebrae. Note that the direction of the needle is at right angles to the spinal column.

B: Often the needle is directed caudally for the search of the first rib, which is unnecessary. Puncture of the pleura and resulting pneumothorax, or puncture of the lung with hemoptysis or massive collapse of the lung, may follow.

C: The needle is directed cephalad and may pierce the dural covering of the roots or even enter the intervertebral foramen and puncture the cord.

The injections must be done only after adequate instruction and supervision by the resident staff.

If improvement is to follow cervical sympathetic block, it should be noticed within the next ten minutes; the improvement may then continue. Should a relapse occur, the patient must be given a second injection. We have not given the injections more often than once every twenty-four hours, but possibly they might be given even eight to twelve hours apart if improvement is followed by deterioration.

A total of fifty-seven injections have been made in the 25 patients. More than half of the patients received only one injection, owing to the fact that in our early experience we were not sufficiently aware of the importance of giving the patient further injections if the first seemed useful. Today it is customary to inject the cervical sympathetic chain daily until no further improvement is noted. It also seems that bilateral sympathetic block is more effective, at least in the animal experiment,[25] but no simultaneous injections have been made in this series.

COMMENT

In spite of the theoretic considerations which made it seem unlikely that the temporary elimination of vasomotor tonus of the cerebral vessels would effectively influence the derangement of cerebral circulation following apoplexy, our clinical observations leave no doubt that in properly selected cases, with injections being made at the earliest possible moment, an acceleration of the phase of restitution may be expected. By this we mean that after all cerebrovascular accidents there is present around the ischemic or hemorrhagic infarct a zone of stasis, vasoparalysis and exudation of plasma. This has been seen in the experimental animal through a window in the skull by Villaret and Cachera [15]; they demonstrated that a collateral network develops around and into the infarcted areas and that there are segmental spasms and dilatations of the nonobstructed vessels. They showed that these functional changes must be activated by an irritative sensory lesion of the obstructed vessels, since air embolism, while producing complete vascular block, never was accompanied by such phenomena. Their observations, however, relate to the vessels of the pia, which are known to have more vasomotor control than the intracerebral vessels.

A second observation, which indicates that widespread cerebral damage may occur at a great distance from the original lesion, can be found in the histologic studies of Evans and Scheinker,[11] who observed diffuse cerebral atrophy accompanying focal injuries in head trauma. They reported that the white matter stands the collateral edema and stasis much more poorly and that the hypoxia here is followed by diffuse gliosis. While recently there has been a tendency to minimize the importance of cerebral swelling in concussions, the accurate measurements of White, Brooks, Goldthwaite and Adams [26] showed that edema and congestion are present, fluid being extravasated through permeable anoxic capillary membranes.

The question then arises: Can sympathetic block relieve such stasis by (1) releasing the arteriolar spasm proximal to it, (2) by improving venous drainage and thereby decreasing intraventricular and intraspinal pressure or (3) by so affecting the extracerebral portions of the carotid arteries that more blood may be brought to the brain? Such studies are now under way.

On the basis of our conception, the following therapeutic measures seem indicated in acute cerebrovascular accidents: For patients with cerebral embolism, an oxygen tent, slowing of rapid fibrillation, stellate block and anticoagulants are ordered. "Dicumarol" may be administered for weeks and months according to a schedule discussed elsewhere.[27]

For patients with cerebral thrombosis, an oxygen tent, venesection in case of hypertension, stellate block and release of increased spinal fluid pressure are indicated.

For patients with cerebral hemorrhage, an oxygen tent, slow spinal drainage and neurosurgical consultation concerning possible evacuation of clots may be considered. No sympathetic block need be done.

In all three varieties of apoplexy, hypertonic sucrose solution or a concentrated solution of albumin with 5 to 7½ grains (0.3 to 0.5 Gm.) of aminophylline, given intravenously, should improve cerebral edema. There is some evidence that aminophylline lowers spinal fluid pressure,[28] and its use seems to us more rational than the extreme dehydration advocated for patients with cerebrovascular accidents or head trauma.

ADDITIONAL MEASURES

Pulmonary Ventilation.—An embarrassed cerebral circulation is greatly handicapped if the oxygen exchange of the lungs is diminished. It is not enough, however, to place the unconscious or slightly cyanotic patient in an oxygen tent and leave him in the half-sitting position. Mucus, bronchial secretion, collects in astonishing quantities in the tracheobronchial tree of the apoplectic patient, just as in head trauma. It is likely that just as in pulmonary embolism [29] and in reflex pulmonary atelectasis following trauma of the chest [30] this "wet lung" is the result of vagal stimulation, which here is of central origin. Since the majority of patients who survive the first forty-eight hours of the apoplectic insult die of pneumonia, postural drainage of the tracheobronchial tree is an important, though much neglected, measure for the unconscious patient. The patient is placed on his side rather than on his abdomen in the cardiovascular case, and the foot of the bed is slightly elevated. Mucus may be aspirated from the mouth and pharynx through a no. 14 French catheter. A metal airway may be inserted if necessary. Aminophylline and atropine may be used if secretion is excessive. It is astonishing how good postural drainage and some pharmacologic inhibition of bronchial obstruction and secretion may clear up neurologic signs due to anoxia and prevent the greatest single cause of mortality.

Nutrition.—If after twenty-four to forty-eight hours the patient is still unconscious, parenterally administered fluids are substituted by hourly feedings through a Levine tube, the patient's protein and vitamin requirements being kept in mind. Dehydration, practiced so extensively at one time in head injuries, need not be carried out, and a fluid intake of 2,000 to 3,000 cc. of liquids may be maintained. A 25 per cent albumin solution injected intravenously gives excellent nourishment and serves more usefully against the wet brain than injected dextrose or sucrose solutions.

Urinary Drainage.—The overdistention of the bladder of the stuporous patient should not be allowed to persist; both retention and incontinence are encountered, and these should be treated according to present day urologic principles. The wet soiled linen greatly contributes to the occurrence of decubitus ulcers.

Sedation.—Stuporous or unconscious patients require no sedation. Restless patients may have phenobarbital 1 to 3 grains (0.06 to 0.2 Gm.), bromides 20 to 60 grains (1.29 to 3.88 Gm.), chloral hydrate 20 to 30 grains (1.29 to 1.94 Gm.) or paraldehyde 1 to 3 drachms (3.88 to 11.65 Gm.) per rectum. For patients with severe restlessness, delirium, intravenous "pentothal sodium" or "amytal sodium" may be needed, but narcotics are to be avoided for several reasons: Their miotic effect prevents the development of localizing ocular signs, they depress the activity of the respiratory and cardiovascular mechanisms, they increase intracranial tension, they may exert undesirable side effects on the gastrointestinal tract and, finally, as sedatives they do not calm the patient any more than the aforementioned, less noxious agents. Generally speaking, the apoplectic patient should have the benefit of the treatment developed by neurosurgeons in cases of head trauma.[31] These principles have not been consistently applied to patients suffering from strokes.

Surgical Exploration in Apoplexy.—This problem is just in its infancy. As Aring[6] pointed out, every massive cerebral hemorrhage above a certain size is fatal. Our mortality in the present series is 77 per cent, and here is a neurosurgical problem which needs to be attacked before the blood reaches the intraventricular system. Ventriculograms and arteriograms may be helpful in localizing the hemorrhage. The indications and results of such clot evacuations in cases of spontaneous intracerebral hemorrhage are yet unknown.

SUMMARY

In the diagnosis of apoplexy it is important to differentiate between cerebral embolism, thrombosis (or softening) and hemorrhage. In treatment the collateral stasis, the vasoparalysis and the edema accompanying the cerebrovascular accident are to be stressed. In 25 patients the cervical sympathetic trunk was blocked with procaine on the side of the lesion. (Other methods of combating cerebral edema and stasis may be added.) Good response was obtained in 19 of these patients. Regain of consciousness and of speech, motor improvement and conversion of flaccid into spastic paralysis were also observed. These results suggest that a less passive attitude should be taken in regard to the treatment of apoplexy.

Hematological Individuality.—The remarkable thing about human and animal blood in general is that no two individuals of any particular species have identical blood properties. In other words, we have a hematological individuality resembling that of our fingerprints. This individuality is the result of a number of substances which are present in the red blood cells. The substances are readily demonstrable by specific antibodies, so that with a particular antigen the blood is either clumped or it is not clumped. There must be some reason why nature put all these agglutinable substances in the red cells; but as physicians we are chiefly interested in the parallelism of this individuality to the results that we observe in skin and tissue transplants. The only successful skin grafts are the autogenous. The individual difference in transplantation results runs parallel to the individuality of the several blood factors in the red blood cells. These substances in the red blood cells are inherited and follow distinct laws of human heredity.—Philip Levine, M.D., Clinical Importance of Rh Factor, *Bulletin of the U. S. Army Medical Department*, February 194

THE NEWER CONCEPT OF ALLERGY TO DRUGS AND BACTERIA

FRANCIS C. LOWELL, M.D.
Boston

The word allergy is used today to signify two rather different concepts. In the narrower sense the word is used to designate the field of diagnosis and treatment of those diseases, especially asthma, hay fever, eczema and urticaria, that follow or are believed to follow exposure to certain substances. In a broader sense the word allergy denotes in addition a variety of hypersensitive states arising in infections or as a result of exposure to drugs, antibiotics and the numerous preparations of plant or animal origin used in the modern practice of medicine. In this latter sense the field of allergy is indeed a wide one.

A large number of important diseases are being considered or studied from the point of view of a possible allergic mechanism, many of which lie entirely outside the province of the great majority of practicing allergists. By way of illustration, there may be mentioned glomerulonephritis,[1] rheumatic fever,[2] rheumatoid arthritis, periarteritis nodosa,[3] polyneuritis, Reiter's disease, Löffler's syndrome, disseminated lupus erythematosus, dermatomyositis, sympathetic ophthalmia, erythema nodosum and a number of other skin conditions, sarcoid, scleroderma, eosinophilic granuloma of bone,[4] the postinfectious encephalitides, Schilder's disease, multiple sclerosis and encephalitis following prophylaxis for rabies.[5] The list could doubtless be extended considerably. There is increasing experimental evidence to support the view that in the pathogenesis of some of these conditions allergy to drugs and bacteria or bacterial products or allergy associated in some manner with infections plays an important role. The evidence for this is derived largely from animal experimentation involving in many instances improved methods for the production of the hypersensitive state. Striking pathologic lesions have been shown to follow the induction in the experimental animal of "autoimmunity" against a single organ such as the kidneys or the central nervous system, observations which may have an important bearing on certain diseases in man.

The experience of every physician practicing medicine today includes many instances of allergic reactions to drugs and bacteria, but the understanding of such reactions remains incomplete. The difficulty lies in the absence of a direct means of investigating these conditions. The methods which are ordinarily used in immunologic problems do not seem to apply in the great majority of drug or bacterial allergies, in which

circulating antibody is apparently absent or, if present, may be unrelated to the hypersensitive state. Experiments in guinea pigs have shown, for example, that sensitization to simple chemical compounds may be readily established but that circulating antibody may be undetectable. Passive transfer of the contact or tuberculin type of sensitivity cannot be achieved by injecting serum from an allergic animal into a normal one. However, a transient passive sensitization of this type has been shown to follow the injection of peritoneal exudate containing large numbers of living white cells from a sensitive animal into the abdominal cavity of a normal animal.[6] Thus in these instances the ability to sensitize resides in the cell. Similarly, cells washed free of serum obtained from tuberculous guinea pigs [7] or rabbits [8] are killed by exposure to tuberculin in tissue culture, and this susceptibility to tuberculin is transmitted to the descendants for at least several generations.[8] When under appropriate conditions circulating antibody for old tuberculin appears in the serum, allergic reactions associated with it are usually of the anaphylactic type.[9] In these circumstances allergic shock or the immediate type of cutaneous reaction may follow injection of tuberculin into the sensitive animal. However, damage to cells in vitro in the presence of the antigen occurring only on the addition of circulating antibody has not been demonstrated.

Application of the usual immunologic technics is limited not only by the occurrence of allergy to drugs and bacteria in the absence of circulating antibody but also by the difficulty of defining the role of a circulating antibody in the production of allergic disease. A considerable number of infectious diseases, for example, are associated with agglutinins which appear to bear no relation to the infectious agent. The best known of these is the Wassermann antigen, for which reagin may appear not only in syphilis but in malaria, leprosy, vaccinia, trypanosomiasis, kala-azar, infectious mononucleosis, Vincent's infection and occasionally in other infectious states, constituting in all but the first listed, namely syphilis, the biologically false positive reaction. Other antigens of tissue or bacterial origin may also react with the blood of patients with certain infections, as in the agglutination of proteus OX 19 by serum from patients convalescing from typhus, agglutination of sheep cells in infectious mononucleosis, cold hemagglutinins and complement-fixing antibodies from normal mouse lung in primary atypical pneumonia of unknown cause,[10] agglutination of an "indifferent streptococcus" in the same disease,[11] "antibody" for the somatic C substance of the pneumococcus in many infectious states [12] and capsule-swelling activity for the pneumococcus of type 27 and others.[13] Nothing is known concerning the role of these various serologically reactive constituents that appear in the serum with no apparent relation to the causative agent of the disease, nor, with rare exceptions [14] do they give rise to any difficulties in the person possessing them. Finally, "natural antibodies" for various rabbit tissues have been demonstrated in normal rabbits,[15] and most normal persons have circulating "natural antibody" for type 7 pneumococci.[16] Thus the demonstration of an agglutinin or precipitin or any other serologically reactive factor in the serum of a person with suspected allergic disease adds little to the knowledge of the condition unless it can also be shown precisely what change the component is capable of bringing about physiologically or pathologically.

The successful use of cutaneous tests as a diagnostic aid in hay fever, asthma, sensitivity to heterologous serums and some other conditions has led many workers to adopt them in the study of allergy to bacteria. A number of considerations indicate, however, that the interpretation of such tests made with bacterial antigens must necessarily be difficult or impossible unless a great deal of precise information is available concerning the testing material and the person to be tested. The difficulty stems from the complex antigenic composition of bacteria [17] and from the frequency and variety of exposure to bacteria or their products both in health and in disease. A further complicating factor is the presence in widely different bacterial species and tissues of antigenic components which may be identical or similar. Thus the demonstration of reactivity of the skin to a bacterial vaccine, for example, need not mean that allergy has developed as a result of exposure to the organism from which the vaccine was made. On the contrary, the reactivity of the skin may depend on previous exposure to some entirely unrelated organism which contained one or more similar allergenic or antigenic components. A further difficulty arises from the necessity of gaging sensitivity of the mucous membrane, or of the pulmonary or other tissue by the reactions elicited in the skin. Thus the investigation of allergic states of bacterial origin by means of cutaneous tests can hardly be expected to yield clearcut results.

Reactions of an allergic nature may be grouped, perhaps somewhat arbitrarily, in three main categories differing, superficially at least and possibly fundamentally, in the matter of antibody. First there are those states associated with and apparently dependent on the production of a heat stabile antibody, which when present in the blood is demonstrable in vitro by the usual immunologic technics and in vivo by anaphylaxis, the Arthus reaction, the immediate type of cutaneous reaction and the capacity to sensitize passively. It is this type of antibody that is used for serologic diagnosis and for passive and, for the most part, active immunization against certain infections and toxins. There is a striking paucity of allergic diseases in man, the pathogenesis of which is clearly dependent on the allergic reaction giving rise to this type of antibody. A few examples are erythroblastosis fetalis, certain transfusion reactions, serum disease and the Arthus reaction. However many additions will probably be made to this brief list in the future.

A second and large group is characterized by an antibody differing from the first in that it is heat labile, has never been shown conclusively to react in vitro and is capable of producing prolonged passive sensitization of tissues, especially skin, into which it is injected. This antibody, though most commonly seen in "atopic" persons, some of whom exhibit extreme degrees of hypersensitivity, may nevertheless develop in anyone under suitable provocation, as for example, in trichinosis. Allergic reactions to drugs and bacteria rarely fall into this group.

The third and probably the largest group is characterized by the absence of demonstrable antibody in the circulating blood. It includes most of the recognized allergies to drugs and infections and indeed may not be homogeneous. Reactions of the tuberculin type may follow injection of the allergen, or a local superficial reaction may often be produced by a patch test. In many instances of drug allergy, however, no local lesion can be produced and the allergic reaction, usually systemic, only appears when the drug is absorbed into the circulation.

Classification of allergic reactions is necessarily difficult in view of the present ignorance concerning mechanisms. A further confusing factor is the frequent coexistence of more than one type of allergy, which so frequently occurs in infections. For example, an immediate type of cutaneous reaction to the capsular polysaccharide of the pneumococcus may coexist with the tuberculin type of reaction to a protein contained within the bacterial cell. The first is passively transferable to animals and man with animal serums having a high precipitin titer for the capsular substance. An example of another kind is the coexistence of two types of antibody for a single antigen in treated pollen-sensitive subjects[18] and in a diabetic patient exhibiting both allergy and resistance to insulin.[19]

The role of the cell in the development and expression of allergic reactions needs special emphasis. The great majority of the diseases of supposedly allergic origin previously mentioned are associated with damage to or death of tissue cells, which leads in some instances to the death of the entire organism. As has been stated, death of allergic cells may follow exposure to the allergen in vitro and leukocytes from the peritoneal exudate of an allergic animal may confer a transient sensitivity on a normal one. There is also considerable evidence, in addition to that implicating the reticuloendothelial system,[20] that lymphocytes and plasma cells are directly responsible for the elaboration of antibodies[21] and that liberation of antibodies may be influenced or perhaps controlled by the endocrine system.[22] The importance of the cell is also illustrated by the "flare-up" reaction seen during treatment with pollen extracts and in drug allergies as well as by the focal reaction in tuberculosis following the injection of tuberculin. An interesting example of this type of response has been described recently[23] in persons who were vaccinated with a brucella antigen and in whom brucellosis later developed. A direct approach to the behavior of various types of hypersensitive cells on contact with the allergen is needed. Adaptation of modern methods of tissue culture might well provide a technic applicable to problems in human allergic disease.

The conditions under which exposure to a drug or other potentially allergenic substance occurs may be of the greatest importance so far as the development of the hypersensitive state is concerned. This is borne out in the first place by experience with the local application of sulfonamide drugs to eczematous areas of the skin. Allergic reactions were so frequent and severe that their prolonged use on such areas has been cautioned against repeatedly.[24] In the second place, extensive experience with animals has shown that the development of both the hypersensitive state and antibody may be greatly enhanced by appropriate procedures. Many of these are associated with prolonged and slow absorption of the antigen from the injected site, as in the use of alum-precipitated toxoids or the antigen in liquid petrolatum and a hydrous wool fat base, but it seems unlikely that the enhanced response is due to these factors alone. Especially good results have been obtained when the antigen is mixed with bacteria or their products which cause an inflammatory reaction. Thus lens antibody was readily produced in rabbits by injections of lens substance mixed with staphylotoxin,[25] renal lesions were produced in rabbits and rats by the injection of homologous kidney mixed with streptococcic extracts[26] and striking lesions of the central nervous system were rapidly produced in monkeys by the injection of monkey brain incorporated in liquid petrolatum and a hydrous wool fat absorption base with added tubercle bacilli.[27]

Morgan, I. M.: Allergic Encephalomyelitis in Monkeys in Response to Injection of Normal Monkey Nervous Tissue, J. Exper. Med. **85:** 131 (Jan.) 1947.

A consideration of the role of bacteria or their products in enhancing the development of hypersensitivity to an antigen injected in mixture with them raises important questions with regard to allergy to bacteria. It is commonly stated, for example, that glomerulonephritis represents an allergic reaction to the streptococcus. However if glomerulonephritis in man is regarded in the light of the experimental production of glomerular lesions in animals with antibodies for kidney tissues, a more reasonable assumption would be that this disease arises because autoantibodies to kidney develop in consequence of a streptococcic infection acting as an adjuvant. According to this view, allergy to the streptococcus itself need not occur. The lesions of rheumatic fever have been considered in a similar manner[28] as have also the postinfectious encephalitides.[5] It appears therefore that two types of allergy associated with infections are possible, one resulting from development of hypersensitivity to the infecting agent itself and the other occurring as a result of autoimmunization due to the adjuvant action of the infecting agent.

SUMMARY

Investigation of allergic states is made difficult by the lack of satisfactory methods, those most commonly employed having serious limitations and often giving rise to confusion. There is clear need for more direct methods of approach, especially in the clinical study of allergy. Experimentation on human subjects under controlled conditions, such as has been done in a few instances, may find much wider application than it has hitherto.[29] Tissue culture[30] has yielded valuable information, and this appears to be a promising line of investigation.

The tendency today is to ascribe a wide variety of diseases to an allergic origin in the pathogenesis of which drugs and bacteria appear to play an important role. The conditions under which exposure to a substance occurs appear to have a direct bearing on the development of the allergic state. The striking effect of adjuvants in this regard provides a potent tool for investigation. Especially important is the accumulating evidence that bacteria or their products may act as adjuvants and be instrumental in bringing about the development of autoantibodies with tissue specificities.

ABSTRACT OF DISCUSSION

Dr. M. G. Bohrod, Rochester, N. Y.: Anyone who is not a practicing allergist but who is interested in allergy must find it gratifying to see the practicing allergist concerned with this larger group of diseases. A wide list of diseases is being discussed as either allergic or nonallergic. The tendency is to conceive of this list as temporary only in the sense that single diseases will either be put on the list permanently or dropped permanently. It may be that neither will happen. Instead there will be the realization that allergy is a mechanism which is concerned in only some (or many, few or occasional) instances of these diseases or in other words that it is only one of the mechanisms which may produce the disease. I have been fascinated by the concept of Hans Selye. Those who know about this work will recognize the "shock reaction," the "energy of adaptation" and the "diseases of adaptation" that occur. His list of the diseases of adaptation is practically identical with the list that Dr. Lowell gave. In Selye's concept allergy or the allergic mechanism would be one of the kinds of shock reactions which would use up the energy of adaptation. It would also explain why factors other than the antigen itself can produce the disease once it has been started by an allergic mechanism and how, on the other hand, allergens can perpetuate the disease. Specificity is a relative term. Probably no antigen is absolutely specific; theoretically, at least, another substance can be found or produced so closely related chemically or physiologically that it will elicit the same reaction as the original antigen. The same degree of relationship need not exist for all substances. Dr. Lowell has indicated the importance of some of the nonspecific mechanisms in establishing or maintaining allergic states. I should like to point out one which is still not proved but which, if proved, may indicate how a mechanism which is "nonspecific" on an antigen-antibody level may be "specific" on a chemical level. For a couple of years I have been pointing out the similarity of certain of the pathologic features of asthma with vitamin A deficiencies in the lung and with other diseases connected with vitamin A deficiencies. I have been careful to point out that I do not know if there is any relation to asthma itself; it may be purely secondary. But recently it has been shown that vitamin A and substances closely related to it have antihistaminic effects.

SURGICAL EXPERIENCE WITH TUMORS OF THE PITUITARY GLAND

FRANCIS C. GRANT, M.D.
Philadelphia

One thousand and one tumors of the brain were verified in the neurosurgical service of the University and Graduate Hospitals of the University of Pennsylvania, between Jan. 1, 1936 and Jan. 1, 1947. Of these tumors, 101, or 10 per cent, were of pituitary origin, either intrasellar adenomas or extrasellar craniopharyngiomas. It is with the results of combined surgical and roentgen ray therapy of these lesions that this paper is concerned. Since intrasellar and extrasellar tumors differ somewhat in clinical manifestations and greatly in their response to either type of therapy, the two groups will be considered separately.

What benefit may be expected from the treatment of a pituitary tumor of either type? In none of the cases in this series in which a craniopharyngioma was verified were the glandular symptoms materially improved by any therapy—irradiation, endocrinologic or surgical. In 3 out of 4 cases in which diabetes insipidus was noted, complete relief resulted from evacuation of the cystic tumor. To balance this, however, in 2 other instances diabetes insipidus was a consequence of operation, requiring control with posterior pituitary injection U. S. P. ("pituitary extract"). Of the adenomas of the pituitary gland, 10 were of the eosinophilic type, 6 being associated with definite acromegaly. After irradiation therapy and surgical evacuation of the gland, little or no change in the acromegalic symptoms was noted. Of the 71 cases of adenoma, whether eosinophilic or chromophobic, loss of sexual potency, accompanied with pronounced menstrual disturbance, usually complete amenorrhea, was noted in 65. In only 1 of the 41 female patients was menstruation restored to normal rhythm or amount with combined therapy. In 2 of the younger male patients mild improvement in sexual power occurred.

The principal responsibility assumed by the medical attendant, whether surgeon, roentgenologist or endocrinologist, in a case of pituitary neoplasm is restoration or preservation of vision. It is to this end that all

treatment in such cases should be directed, since glandular dysfunction cannot be materially benefited. Visual function can be restored, or at least preserved at a useful level, by an intelligent combination of irradiation and surgical therapy.

In a previous paper,[1] the results obtained with the combined therapy of pituitary adenomas were outlined. No reason for change in these methods has appeared. A patient with evidence of an intrasellar tumor of the pituitary gland, glandular dystrophy, roentgenographic evidence of changes in the sella, contraction of one or both temporal visual fields or a retinoscopic report of early atrophy of one or both optic nerves may be advised to undergo irradiation therapy or surgical exploration. If the visual acuity is better than 6/9 in each eye, and if the atrophy of the optic nerve is not advanced, irradiation therapy is indicated regardless of changes in the visual fields or the sella. However, if visual acuity is less than 6/9 in either eye, especially if the impairment in vision has advanced with any speed, say, in less than six months, to a complete unilateral or bilateral cut of the temporal field, and if the atrophy of the optic nerve is pronounced in either eye, then surgical intervention must be seriously considered. In any case in which visual loss is rapid and severe, surgical evacuation of the gland will relieve pressure on the optic nerves adequately and promptly and produce a more complete restoration or preservation of vision. After surgical collapse of the adenoma, studies of the visual fields and visual acuity are ordered every three months. As long as the fields and the acuity improve or are unchanged, no further treatment is indicated. If progressive contraction of the temporal field or loss of acuity is noted, irradiation therapy is promptly instituted. A careful check on both elements of vision gives accurate information as to the results of therapy and the need for further treatment.

ADENOMAS OF THE PITUITARY GLAND

The adenomas of the pituitary gland, of whatever type, form the more favorable group for either means of treatment. Seventy-one pituitary adenomas, 61 chromophobic and 10 eosinophilic, were verified. In but 7 cases had irradiation therapy been used prior to operation—in 2 cases for three years, in 3 cases for two years and in 2 cases as a single course. In the 71 cases, 85 operative exposures were carried out, with 8 deaths, a case mortality of 11.2 per cent and an operative mortality of 9.4 per cent. Of the remaining 63 cases, 55—46 of chromophobic and 9 of eosinophilic adenoma—could be traced through the Tumor Registry.

Table 1 gives the period of postoperative survival. It is noteworthy that irradiation therapy was required in 16 of the 27 cases with a survival period of five years or more. Four of the patients with chromophobic adenoma have died—1 within six months, of recurrence of the tumor; 1 in two years, of diabetes; 1 eight years after operation, of cancer of the breast, and 1 ten years after operation, of recurrence of the tumor. Forty-one of the patients with chromophobic adenoma are still living, the average period of postoperative survival being five years. Of the 9 patients with eosinophilic tumors, 2 died—the one two years after operation, of recurrence, and the other four years after operation, of pneumonia. Eight survivors have lived an average of four years since operation. It is interesting that there were no operative deaths among the 10 patients with eosinophilic tumors.

In our previous article on pituitary adenomas, the method devised by Snell for determining visual functions was used to compare the results of operative treatment and those of combined surgical treatment and irradiation. In the present series of 55 cases of adenoma, both eosinophilic and chromophobic, no irradiation therapy was received in 24, and both types of treatment were used in 31. Of the 24 cases in which irradiation was not employed, results of treatment were good in 14 and unsatisfactory in 10. The average preoperative visual efficiency was 34 per cent. In 14 cases with an average follow-up period of five years, visual efficiency increased to an average of 58 per cent. In 10 cases with less satisfactory improvement, the increase in visual acuity during an average five year period of observation was from 29 to 44 per cent. In the 31 cases in which combined irradiation and surgical treatment were used, visual acuity improved from 32 to 68 per cent in 19 and from 31 to 54 per cent in 12. The improvement has been maintained over an average period of five years (table 2).

TABLE 1.—*Period of Postoperative Survival in Fifty-Five Cases of Adenoma of the Pituitary Gland*

	No. of Cases
Surgical treatment only	
Visual acuity improved from 34-58%	14
Visual acuity improved from 29-44%	10
Average improvement with surgical treatment alone, 31%	
Combined irradiation and surgical treatment	
Visual acuity improved from 32-68%	19
Visual acuity improved from 31-54%	12
Average improvement with surgical treatment and irradiation, 42%	

* The series included 45 cases of chromophobic and 10 of the eosinophilic type.

An operative mortality of 9.4 per cent seems high, considering that the procedure used is a small craniotomy with intracapsular enucleation of the tumor. In but 1 case was complete removal carried out, in this instance under the misapprehension that the tumor was a meningioma. The craniotomy is made on the side of the eye showing the greater loss of visual acuity, although a right-sided bone flap is turned down whenever possible. The dura is elevated from the orbital plate and cut along the sphenoid ridge, so that the approach, for the most part, is extradural. The olfactory nerve, the internal carotid artery and the optic nerve are identified, the last structure usually being stretched taut over the intrasellar tumor. The capsule of the adenoma is exposed, coagulated and incised. After incision of the capsule, a material, about the consistency of tooth paste, usually extrudes, although the contained material may be more fluid and bloody. In 3 instances of subsequently proved adenoma, yellow fluid, much like that seen in a craniopharyngioma, was obtained. This is important, since a cyst containing yellow or yellow-green fluid has been considered pathognomonic of a craniopharyngioma. However, no typical crystals could be identified in the 2 cases in which sufficient fluid for study was collected. After incision of the capsule and extrusion of its contents, the adenoma collapses, relieving pressure on the optic nerves and chiasm. Sufficient intracapsular material for pathologic verification is obtained by gentle curettage of the interior of the tumor, and then further removal of its contents is accomplished by suction. No attempt is made to tease out the capsule. At most, further collapse and contraction may be produced by coagulating it. The possibility of injury to the closely adjacent carotid artery is the reason for conservative handling of these adenomas. In 2 of the 8 fatal cases in this series, rupture of a carotid vessel, with hemorrhage and damage to the brain during its control, was the direct cause of death. In another, nonfatal, case, in which operation was performed in 1936, the right carotid artery was torn and successfully clipped. The woman has survived ten years, with 6/9 vision in the left eye and 20/70 vision in the right eye, an improvement over the preoperative level of 6/22 and 1/60, respectively. She is badly handicapped by a spastic hemiplegia of the left side, which has spoiled an otherwise happy result. The other 6 fatal cases fall into two groups. In 3 cases (2 women and 1 man) there was a history of two to three years of visual loss, headache, gonadal insufficiency, weak spells and intolerance to cold. The basal metabolic rates in these 3 cases were —30, —34 and —41 per cent, respectively. Roentgenographic studies showed a ballooned sella with preservation of the posterior clinoid processes. In 2 of these cases prolonged irradiation therapy had been given, without improvement. In each of the 3 cases a small transfrontal flap was turned down, with use of local anesthesia, the tumor gutted and material removed for verification. After this simple procedure, the patients became stuporous and never recovered consciousness, dying five, nine and twelve days, respectively, after operation. Autopsy in 2 of these cases showed atrophy of the adrenal glands, thyroid and ovaries or testes—a polyglandular failure. A satisfactory test for adrenal insufficiency would be of value, so that surgical measures could be avoided in cases with severe damage to the adrenal cortex. Certainly, the administration of adrenal cortex extract is of little benefit. But the operative mortality in these cases of generalized glandular insufficiency is high, and surgical attack should be undertaken with caution.

6 years	1		
7 years	1		
10 years	1		

In the 3 remaining fatal cases the adenoma was observed to have spread beyond the sella and involved adjacent structures. In all these cases roentgenographic study revealed destruction of the sella with disappearance of the posterior clinoid processes. In 1 case ptosis of the eyelid was present; in another, diplopia and a Foster Kennedy syndrome, and in the third, loss of the sense of smell and choked disks. A large subfrontal tumor, bilateral in 1 case, unilateral in the second, was observed. The tumor in the third case passed backward to involve the third ventricle and extend through the incisura. In 2 of these cases irradiation therapy had been given, without benefit. Death was accompanied with hyperthermia in every case.

These cases were all of old, burned-out chromophobic adenomas. Pituitary function and, therefore, polyglandular activity were at a very low ebb. Apparently, simple evacuation of the adenoma in such circumstances is enough to abolish completely what little pituitary function remains. In this connection, it is interesting to note that in the 10 cases of eosinophilic tumors, in which the pituitary gland is overactive, no deaths followed operative intervention. The changes in gonadal function, loss of libido, amenorrhea, a low basal metabolic rate, lethargy and intolerance to cold may all be as apparent with an eosinophilic adenoma as with the chromophobic type. But pituitary function does not seem to be as severely impaired and can carry the patient through surgical evacuation of the gland. Furthermore, the eosinophilic adenomas do not tend to overflow and escape from the sella, as does the chromophobic type, an important point to be remembered when surgical treatment is indicated.

CRANIOPHARYNGIOMAS

The prognosis for these tumors is discouraging. Unfortunately, they seem to be entirely unresponsive to irradiation; consequently, surgical attack is indicated. All the complications inherent in the position and origin of these tumors arise to plague the surgeon. Many of these lesions, as is to be expected from their congenital origin, occur in children. The Fröhlich syndrome is too well known to need further description. Dysfunction of the pituitary gland, as well as changes due to suprasellar pressure on the hypothalamus and frequent entanglement of important branches of the carotid artery in the tumor, make surgical measures, whether conservative or radical, extremely hazardous.

This series includes 30 cases of craniopharyngioma. Death occurred in 11 cases—after operation in 10, and in the hospital, without surgical intervention, in 1 case. Forty operative procedures were carried out in these 30 cases—a case mortality of 35 per cent and an operative mortality of 25 per cent.

The diagnosis of these lesions is not particularly difficult. The presence of Fröhlich's syndrome in a child or a young adult, lack of physical development and pronounced retardation in appearance of the secondary sexual characters, as well as roentgenographic evidence of calcification above the sella, are characteristic. Twelve of the patients were under 24 years of age and 9 showed the customary Fröhlich syndrome, whereas of the 18 patients over 24 years of age only 3 had hypopituitary features. Of 28 cases in which roentgenograms were available, a calcified mass appeared in or above the sella in 13, sellar enlargement without a calcified mass was present in 10 and the sella was apparently normal in 5. Of the 20 patients who survived operation, 9 have since died, so that 19 of the 30 patients are known to be dead. Of the remaining 11 patients, 3 have lived a year; 3, for two years; 2, for four years, and 3, for six, seven and ten years each.

The cause of death in the 18 cases was as follows: In 1 case, an 18 year old youth, who had the build and facies of a child of 10, was admitted in stupor, with a temperature of 104 F., and never recovered consciousness. Autopsy showed a suprasellar cyst, containing about 60 cc. of yellow fluid. The pituitary gland, thyroid, adrenal glands and testes all exhibited extensive atrophy. In a second case the patient was admitted in the same condition, with a cleancut Fröhlich syndrome. The cyst was tapped through a burr hole and 40 cc. of "motor oil" fluid removed. Death occurred twelve hours later. Autopsy revealed general glandular atrophy, similar to that in the preceding case. In 4 cases death followed injury to a major branch of the carotid artery during an attempt at complete extirpation of the calcified mass. In 2 cases the cyst was attacked through the corpus callosum. In each case the dystrophy was of the Fröhlich type; local anesthesia was used; the patient never roused after operation and died within forty-eight hours with hyperthermia. Autopsy showed the polyglandular atrophy which is associated with this condition. In 2 cases in which the right frontal lobe was amputated to obtain better access to the tumor, which was completely removed, death was accompanied with hyperthermia. The patients were 34 and 37 years of age, respectively, and showed few signs of involvement of the pituitary gland. In 1 of them the presence of a craniopharyngioma was unexpected, as the sella was normal and no suprasellar calcification could be seen on the roentgenograms. Autopsy in these 2 cases showed general glandular hypoplasia with less involvement of the adrenal glands than might have been expected.

The problem in surgical treatment of a craniopharyngioma is threefold: to escape hyperthermia from damage to the hypothalamus, to prevent complete glandular collapse after operation and to avoid damage to the carotid artery.

SUMMARY

In treatment of adenomas of the pituitary gland of the chromophobic and eosinophilic types, the results of combined surgical and irradiation therapy are more effective than surgical measures alone. The suprasellar, congenital tumors, the craniopharyngiomas, have a poor prognostic outlook. They are not radiosensitive. Surgical reports show a high mortality, with few survivors for any length of time.

3400 Spruce Street.

ABSTRACT OF DISCUSSION

DR. JAMES L. POPPEN, Boston: Craniopharyngioma, in my experience, has been the cause of the highest mortality of any cerebral tumor surgically removed. The tumors which are not fixed to the optic chiasm are usually firmly adherent to the circle of Willis and may extend into the third ventricle. The fixation to the chiasm presents a more favorable condition. If one is fortunate enough to encounter tumors of that type, the mortality will be low and the percentage of recurrence less high, since the growth can be removed more radically. My colleagues and I have no definite criteria in the visual fields and the visual acuity by which we decide when roentgen therapy should be instituted, or when surgical measures should be resorted to. Roentgen therapy is instituted in all cases prior to operation if vision is not in immediate jeopardy. There is no question that roentgen irradiation may initiate an emergency; therefore, any patient whose visual acuity is low should be given roentgen treatment in the hospital, and the acuity should be checked daily; any subjective complaint, such as the appearance of scintillating scotomas, during the interval between treatments, should be regarded as ominous. In 3 of our cases this symptom preceded complete, sudden blindness. Even though surgical measures were instituted immediately, vision returned slowly. The optic nerves seem to tolerate gradually increasing local pressure, with vision returning fairly promptly in the bitemporal region of blindness, but will not tolerate sudden, severe pressure, such as is initiated by a hemorrhage into the adenoma as a direct result of roentgen therapy. Another possible complication is a gradual extrusion of adenoma laterally under the temporal lobes, even though headache may be relieved by this spontaneous decompression later. Successful removal, however, is almost impossible. We are inclined to be as radical as possible in removal of the capsule of the adenoma, care being taken to preserve the stalk of the pituitary gland. We have not carried out replacement glandular therapy routinely before operation in our cases. Death, when it occurred in our cases, was due to actual surgical complications, such as hemorrhage, postoperative edema in the region of the hypothalamus or infection. In 2 of the 4 cases of Cushing's disease (pituitary basophilism) complete acute collapse of the endocrine system occurred. Intensive replacement therapy had no beneficial effect. Death took place within two days in each case. One can by no means be smug about the results of treatment of pituitary tumors. The outlook is not so favorable as had been assumed before careful evaluation of the results.

DR. MAX PEET, Ann Arbor, Mich.: Dr. Grant's mortality rate is considerably lower than ours at the University of Michigan. We have not used his criteria for evaluation of roentgen therapy versus operation. So many factors may influence visual acuity that we have not considered this question of particular importance; rather, the question has been whether we should give roentgen therapy or operate immediately. With respect to the rapidity of visual loss, if a patient's visual fields, as taken by an outside ophthalmologist, have shown little change over a number of months, we prefer to use roentgen therapy. On the other hand, if the patient or the physician has noticed rapid loss of vision, we believe the situation is a surgical emergency and that the patient should have the privilege of being admitted to the hospital much earlier than in his normal turn. Early in my experience we operated in all cases. Then, we swung completely to roentgen therapy, and for a short time all our patients were treated with roentgen radiation. But we were discouraged with the results, especially in patients who had had rapid loss of vision. The vision of some of these patients did not improve. In fact, visual loss seemed sometimes to be accelerated. We returned to surgical treatment. Now in the cases of chromophobic adenomas, operation depends on the rapidity of loss of vision. We have not operated on a patient with acromegaly for many years. Our therapeutist has been very successful in treating such patients, and none of them have required operation. On the other hand, I can see no reason for using roentgen therapy on the child, or even the adult, with evidence of craniopharyngioma. Irradiation has no effect on this lesion. This tumor must be operated on, even though the mortality rate is much higher than that for the other types. We have been rather successful in operating on the adenomatous craniopharyngiomas, being particularly careful not to cause traction on the floor of the third ventricle. We have had cases of diabetes insipidus after operation, although we had been extremely careful not to damage the brain. As a rule it was temporary and was managed satisfactorily with posterior pituitary injections. Occasionally, there has been permanent damage, and the patient has had to have injections of pituitary daily, or perhaps oftener, for many years. We have not routinely followed our operations with irradiation. I think we do a slightly more radical procedure than Dr. Grant. I want to congratulate him on a brilliant piece of work.

DR. OSCAR HIRSCH, Boston: My approach to tumors of the pituitary gland is by the endonasal route. This method is based on the submucous resection of the septum. This resection is continued as far as the anterior walls of the sphenoid sinus and through the sphenoidal cavities to the enlarged sella. Physicians who have never seen the operation have usually two objections: first, that the operation is performed through a contaminated area, and, second, that the surgeon cannot see clearly enough where he is working. I must correct these prejudices. 1. The pia-arachnoid does not even reach the diaphragm. Therefore, the pituitary gland is encased in a pocket formed only by dura. A new pocket is formed between the flaps of the septum, by splitting the septum, as in submucous resection. This pocket has no communication with the nasal cavity except for the first incision. This pocket is therefore relatively free of micro-organisms. The operation is done extradurally. This explains the low mortality rate of 5 per cent, even before the era of sulfonamide drugs and penicillin. Now, I use penicillin and sulfadiazine prophylactically, and there has been no instance of meningitis in the 8 cases in which I have used this medication. 2. After removal of the cartilage and bone of the septum, the two flaps can be spread apart as far as the width of the nose. This space is wide enough to see every millimeter of the field of operation under the reflected light. I have demonstrated this to many spectators with a simple gadget which I carry on my head mirror. The endonasal approach is the method of choice for cystic tumors (which comprise 17 per cent of all tumors of the pituitary gland), and in this way they can be easily emptied. To reopen the cyst in case of refilling is an even simpler procedure. The endonasal method is also the one of choice for all intrasellar tumors which do not interfere with the optic chiasm. Such tumors occur in 50 per cent of all cases of acromegaly. These tumors may even be called sphenoidal tumors. There has been no fatality in the cases in my series in which this method was used, whereas the cranial method has a mortality of 20 per cent, according to Henderson. According to Henderson, the endonasal method is strongly indicated in cases of central scotoma (11 per cent) and in cases of hemianopsia (7 per cent). In all other cases this method must be considered as next of choice to the cranial method, especially if the previous roentgen treatment has been without noticeable results. In such cases a cystic tumor is to be suspected. Cases of suprasellar tumors with normal sella are excluded from those in which the endonasal method is indicated and are reserved exclusively for the cranial method. During the period of 1919 to 1937, inclusive, I operated on 277 patients by the endonasal method, and of this number, 194 were alive in 1937, when I reviewed my cases. In this number were 37 patients who had been operated on ten to nineteen years previously, and 23 of this group had permanent improvement.

Dr. Francis C. Grant, Philadelphia: I agree with Dr. Poppen. When a pituitary adenoma has overflowed the sella turcica and invaded either anterior fossa, the surgical problem is serious and difficult. This constitutes an objection to irradiation, for this treatment may give a false sense of security. If a sudden diminution of vision occurs, operation may show frontal invasion by the adenoma. Preoperative glandular therapy would be excellent if an effective preparation of the pituitary gland were available to replace the reduced glandular activity. I am quite in accord with Dr. Peet on surgical indications. With rapid loss of field and decrease in visual acuity, surgical treatment gives a better chance for a greater recovery of vision than any other method of therapy. I was delighted to hear Dr. Hirsch, who did so much to develop and popularize the transsphenoidal approach to lesions of the pituitary gland. Given a certain type of tumor in a definite position, such as a cystic or semicystic tumor bulging down through the floor of the sella into the sphenoid bone, the transsphenoidal route is satisfactory. The modern antibiotic substances should eliminate one of the great dangers—leakage of cerebrospinal fluid and meningitis. The neurosurgeon abandoned this procedure for two reasons: first, only cystic or semicystic tumors could be evacuated by this attack, and second, the method offered technical difficulties. But in the hands of an expert in approaching the sphenoid region, Dr. Hirsch's excellent figures show what can be accomplished.

CHRONIC MYELOGENOUS LEUKEMIA

A Study of 129 Cases in Which Treatment Was With Radioactive Phosphorus

JOHN H. LAWRENCE, M.D.
R. LOWRY DOBSON, M.D.
B. V. A. LOW-BEER, M.D.
and
BRUCE R. BROWN, M.D.
Berkeley, Calif.

The treatment of chronic myelogenous leukemia with roentgen rays is a generally accepted procedure. For many years the local irradiation of the spleen, long bones and other areas of infiltration was the most widely used technic. During the past two decades the method of total body irradiation has gained favor, and many investigators now feel that better control of the disease can be achieved by this procedure. Although cure has not been possible with radiation therapy, studies such as those of Minot and co-workers[1] have shown that comfortable or useful life may be prolonged.

In 1936 it was shown experimentally that when radioactive phosphorus (P^{32}) in the form of sodium mono-hydrogen phosphate was injected into leukemic mice the sites of greatest concentration of the phosphorus atoms were the infiltrated bone marrow and infiltrated soft tissues such as lymph nodes, liver and spleen. Since P^{32} emits beta rays whose half value layer of tissue is about 2 mm., there was thus available a method of giving internal irradiation particularly to those areas infiltrated with leukemic cells.[2] The marrow is further irradiated by virtue of the phosphorus deposition in bone. It therefore seemed clear that if total body irradiation with roentgen rays was an effective form of therapy, then irradiation with P^{32} would prove at least as effective and possibly more so, in view of the decreased radiation dose delivered to normal tissues relative to the pathologic ones. During the past eleven years therapeutic and metabolic studies on 129 patients with chronic myelogenous leukemia have been carried out. Many of these studies have been previously reported, but this is the first attempt to study end results in a large series observed during the period 1936 to 1947.

PREPARATION OF RADIOPHOSPHORUS

The methods used in the preparation of P^{32} and its conversion into isotonic sodium mono-hydrogen phosphate have been previously described.[2e] Recently the

P^{32} has been derived not from the P^{31} (d,p) P^{32} reaction carried out in the cyclotron, but from the S^{32}(n,p)P^{32} reaction which occurs with high yield when ordinary sulfur is subjected to neutron bombardment in the atomic pile. The P^{32} in both cases is identical. The standard solution for several years was one containing 15 to 18 mg. of the salt per cubic centimeter at a p_H of approximately 7.4. During the past year carrier free P^{32} has been used, and the standard solution has been brought to isotonicity by the addition of sodium chloride. Essentially all of the phosphate present in this case is radioactive. The beta ray activity of the solution is standardized against a uranium beta ray source [3] in terms of microcurie radium equivalents. After sterilization it is ready for oral or intravenous administration.

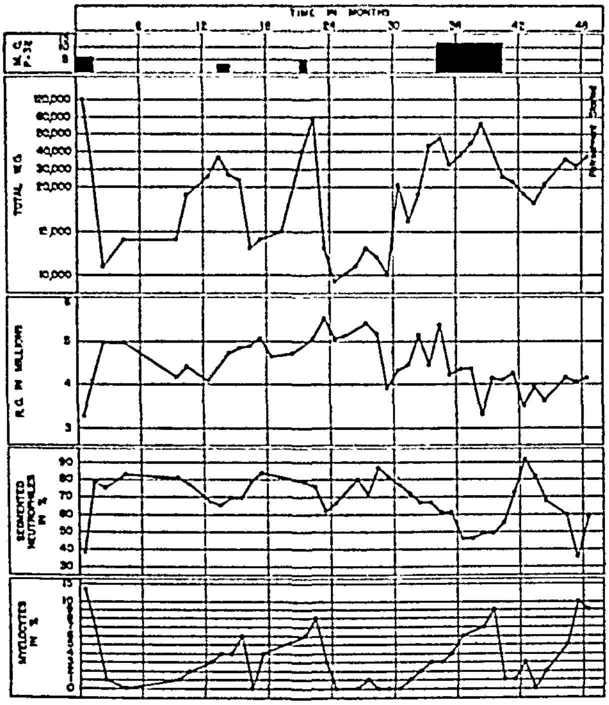

Fig. 2.—Hematologic course of I. J., a 44 year old female patient treated intermittently more than six years with P^{32}. There was a fall of the white cell count and rise of the red cell count accompanied by improvement in the differential after the initial eight week course of 6 millicuries of P^{32}. Satisfactory response followed the next two courses of therapy. The fourth course consisting of 12 millicuries given in six months was followed by less improvement. The disease had become more difficult to control.

DOSAGE

In view of the fact that P^{32} is not distributed uniformly throughout the body, the problem of determination of dose is not an easy one. Several considerations form the basis of this determination. First, experience has been gained in the past with the dosage of 200 kilovolt roentgen radiation given as total body radiation for diseases such as leukemia, Hodgkin's disease, lymphosarcoma, metastatic carcinoma and polycythemia vera.[4] In these studies total doses of 100 to 200 r have been given over a period of six to fifteen days and in some instances even larger doses—as high as 1,200 r over a period of several weeks. Second, it has been calculated that one microcurie of P^{32} per gram of tissue will give a total of approximately 40 r of radiation in a twenty-four hour period.[3] Thus after measuring the percentage of absorption, distribution and rate of excretion of P^{32}, one can roughly calculate the dose to the whole body. In comparing these values with doses given by high voltage roentgen radiation, it must be remembered that in the latter case there is not a uniform distribution of radiation because there is some absorption of the incoming rays by tissue. Third, studies of the lethal doses of P^{32} for mice and monkeys have supplied another guide post.[5] In general they have shown the lethal dose for a 30 Gm. mouse to be around 70 microcuries injected intraperitoneally, and for monkeys around 7 millicuries. The final and most important criteria for dosage determination, of course, are the clinical and hematologic effects, and these criteria apply here as in ordinary conventional radiation therapy.

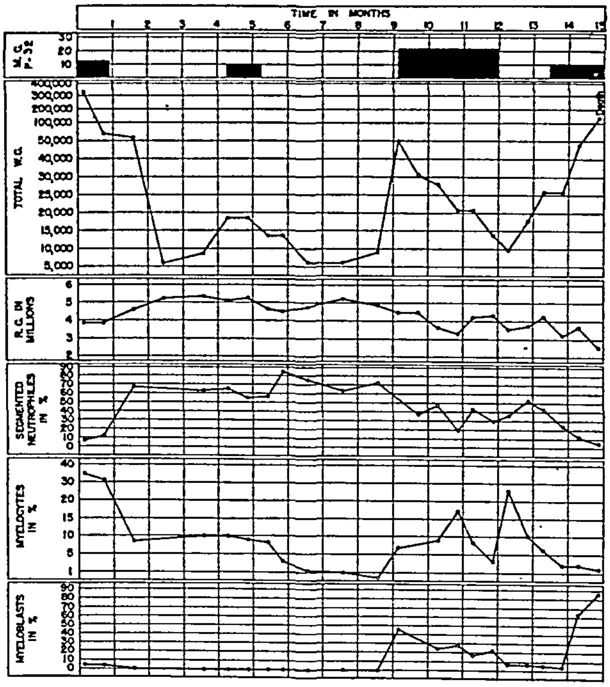

Fig. 3.—I. M., a woman patient aged 44 in whom terminal acute leukemia refractory to further P^{32} therapy developed despite previous satisfactory response. Such a picture with an increase in the number of blasts is not uncommon in chronic myelogenous leukemia, treated by other methods.

Recently Tobias has derived formulas relating the quantity of P^{32}, injected or ingested, to equivalent roentgens of whole body irradiation.[3] These expressions facilitate the conversion of phosphorus doses in millicuries to roentgen equivalents. In order to do this, he has taken into consideration the percentage of uptake, the rate of excretion and the rate of decay of P^{32}. The correctness of these formulas is dependent on the completeness of the data on absorption and excretion; unfortunately these studies on several patients have been extended for only a few days after administration of P^{32}, and one cannot be certain that after many days the excretion rates are the same as during this early period. These formulas are:

For oral administration, total dose in roentgens equivalent physical[6] $= N \times T \times 1.44 \times 0.38 \times \frac{40}{\text{weight in grams}}$;

For intravenous administration, total dose in roentgens equivalent physical[6] $= N \times T \times 1.44 \times 0.52 \times \frac{40}{\text{weight in grams}}$.

In the formulas N represents microcuries and T the half life. The figure 1.44 which appears in both expressions comes from the integration of the dose over infinite time. Absorption and excretion rates account for the factors of 0.38 and 0.52. The figure 40 is the initial dose rate as mentioned previously. Suppose a dose of 5 millicuries is administered to a patient weighing 60 Kg. If there were by chance uniform distribution of the P^{32} atoms throughout the body,[7] the total integrated irradiation would be as follows (after oral administration):

$$5{,}000 \times 14.3 \times 1.44 \times 0.38 \times \frac{40}{60{,}000} = 26 \text{ rep}$$

This irradiation would be the integrated dose spread over a period of many weeks and corrected for slow excretion and decay.

Thus with these guide posts combined with careful hematologic and clinical observation of the patient, the size and frequency of doses are worked out. In general, the doses have been from 1 to 2 millicuries once or twice a week, but doses equivalent to 40 millicuries intravenously over a period of seventy-two days have been given. As is true in the use of roentgen rays and radiation from radium administered locally or by spray, care must be taken with respect to the possibility of overdosage and its deleterious effects on normal cells of the body. In the case of P^{32}, roentgen rays and radium, the normal cells and body constituents of special importance are the megakaryocytes, platelets, normal white blood cells and red blood corpuscles.[8] The extreme variation in the response of patients to irradiation again evokes the clinical maxim that each patient must be individualized. In one patient 5 millicuries given in one or two doses will produce clinical and hematologic responses which are achieved in another patient only after 30 or more millicuries are administered over a period of several weeks. Either amount, in certain cases, may produce leukopenia or platelet depression which is not seen in other patients receiving even larger doses. In some of our earlier work oral doses which now seem extremely high were used. In one instance, as much as 70 millicuries was administered orally over a period of ninety days. In evaluating such a case, however, one must note that the retention of phosphate by the body is less after oral administration than after intravenous administration. At that time, also, the standard for measurement of activity called a microcurie was actually only 0.83 microcurie. Furthermore, the patient was taking iron orally, which caused much of the sodium radiophosphate to pass through the gastrointestinal tract. Also, the P^{32} given was in the form of several grams of sodium mono-hydrogen phosphate, so that the patient had diarrhea much of the time, with consequent poor absorption of the radiophosphate. Decreased absorption of radiophosphate also results when large amounts of inactive sodium mono-hydrogen phosphate are used as carrier.[9] All of these points must be considered when comparing doses and results.

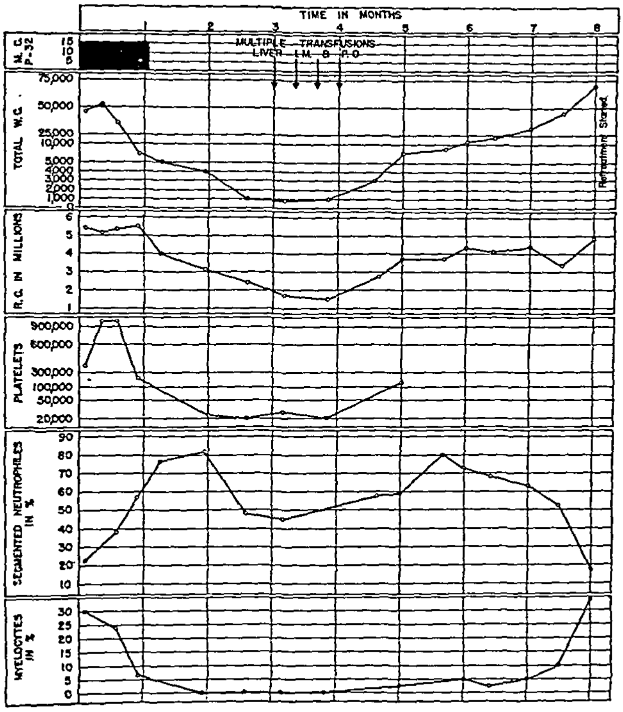

Fig. 4.—H. B., female patient aged 57 demonstrates danger of excessive depression of the bone marrow from overdosage with P^{32}. The patient recovered from this episode of marrow overdepression.

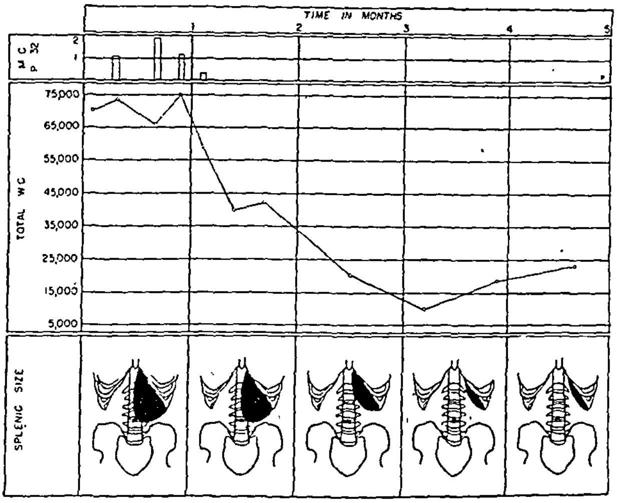

Fig. 5.—M. R., 57 year old woman. Definite improvement of the white cell count and size of the spleen following administration of a small amount of P^{32}.

---

[6] One roentgen equivalent physical (rep) is the dose of ionizing radiation which will deliver 83 ergs per gram.

[7] Actually of course distribution is never uniform; there is localization to a greater or lesser degree in infiltrated tissues and in bone. This relative localization is conditioned by size and frequency of dosage.

DESCRIPTION OF CASES

This study was made on 129 patients[10] who received P^{32} at the Crocker Clinic or the University of California Hospital before March 1, 1946. One hundred of the patients constitute the entire group of patients with chronic myelogenous leukemia seen in one of the clinics up to that date; the remaining 29 were seen in the other clinic, and there was no conscious attempt to select those patients who might respond most favorably. It is our impression that a larger percentage of this group of patients were in a more advanced stage of the disease than one would observe on the average. About one half of the patients had received previous courses of roentgen therapy before referral here or were treated with roentgen radiation by us prior to trial with P^{32}. Likewise, many of them had failed to respond to other forms of therapy and were in poor condition. Half of them were given P^{32} initially, and about one tenth of these later received roentgen irradiation if they had not responded well to P^{32} therapy or if we thought that local roentgen therapy was indicated in addition to P^{32}.

History and Associated Disease.—In studying the histories of these 129 patients, it was of interest to note that in only 2 cases was there a family history of blood dyscrasia. In one case both a brother and a sister had polycythemia; in the other a maternal aunt and her child had leukemia.

Seven of the patients gave a history of malaria. Two patients gave a history of tuberculosis, and in 1 of these pulmonary lesions were found at autopsy. In a third patient fibrocaseous pulmonary tuberculosis and tuberculosis in the adrenal gland were found at postmortem examination. In 3 more instances miliary tuberculosis occurred in patients giving no history of the disease. Holler[11] and Jaffé[12] have pointed out the importance of tuberculosis as a complication and have observed many cases of leukemia come to fatal terminations as a result of miliary tuberculosis.

Age of Onset and Sex.—The ages of this group of patients at onset of first symptoms varied from 10 to 71 years, the average being 40.3 years. The sex distribution was 57 per cent males (73 cases) and 43 per cent females (56 cases). These figures are almost precisely the same as those reported by Minot, Buckman, and Isaacs.[1]

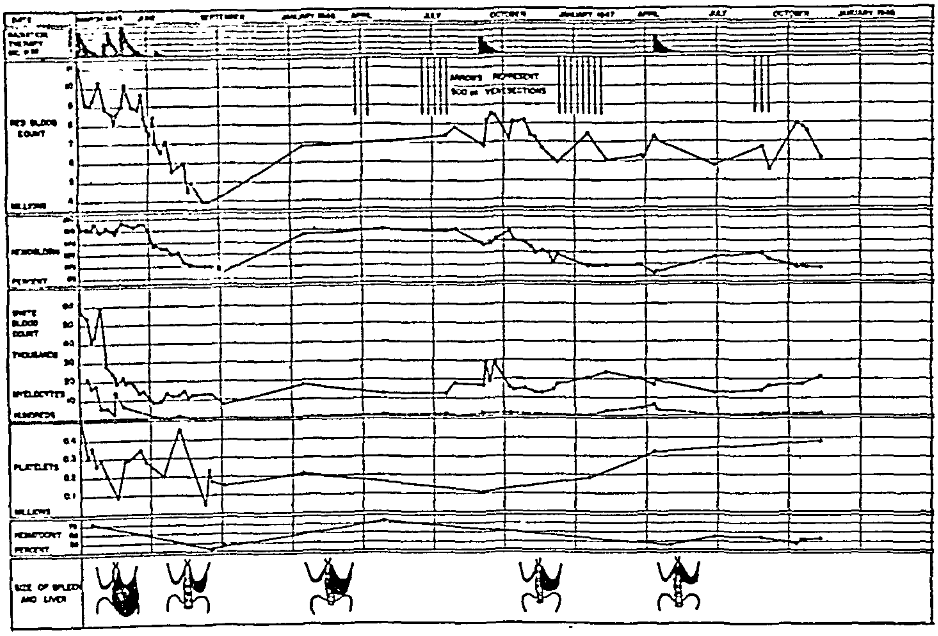

Fig. 6.—A., a man aged 33 with polycythemia vera and associated leukemia, showing a good response of the white cells to the P^{32} therapy.

TREATMENT

After the initial history, physical examination and hematologic study, each patient was seen at intervals varying from several times a week to once every several months, depending on the activity of his disease. More recently we have found that weekly visits for the more active patients are quite satisfactory in general, and the intervals may be prolonged as the disease comes under control. At each visit the patient is questioned regarding symptoms, a complete blood cell count is done, and frequent physical examinations are made as necessary to follow the progress of the disease. As a rule, a sternal marrow study is carried out before therapy is started, again after the completion of the first course, and when indicated thereafter.

The clinical criteria which we have used for treatment have been evidences of activity. Although the sternal marrow offers perhaps the truest indication of the patient's hematologic status, frequent repetition of this study seemed unnecessary.[13] The level and trend of the blood cell counts and the general clinical picture have been the determining factors in deciding when to administer radiophosphorus. In the general handling of these patients, we attempted to give enough P^{32} to bring about clinical and hematologic improvement without damaging the normal cells, careful watch being kept particularly of the megakaryocytes, platelets and the white and red blood cells. At one stage in our studies we attempted to bring the white blood cell counts to near normal and also attempted to arrive at normal, or near normal, differentials. This is no longer being done, for two reasons. First, by arriving at a normal differential and total count one does not insure against recurrence, and, second, such an attempt causes one to have more cases with overdepression of the marrow and decreased production of normal cells. Clinical improvement, with a feeling of increased well-being, improvement in the red cell count, decrease in size of the spleen, decreased perspiration, etc., are all evaluated, and as long as most of these various criteria tend in the right direction, therapy is withheld. On the average, most patients of normal size received from 1 to 2 millicuries per week over a period of from four to eight weeks. Such a course may then be repeated when signs and symptoms of returning activity occur. At one period during this study, a few of the patients were given preventive or prophylactic doses of P^{32} in the hope that recurrence of symptoms and signs would be prevented, but we obtained no evidence that this was an effective procedure. On the other hand, there have been a number of patients who have required therapy only every six to nine months and a few who have required it as infrequently as every one or two years.

---

[10] All patients treated with P^{32} are included and we have complete follow-up on 127 of these patients.

[13] A detailed study of the marrow before, during and after therapy will be reported soon.

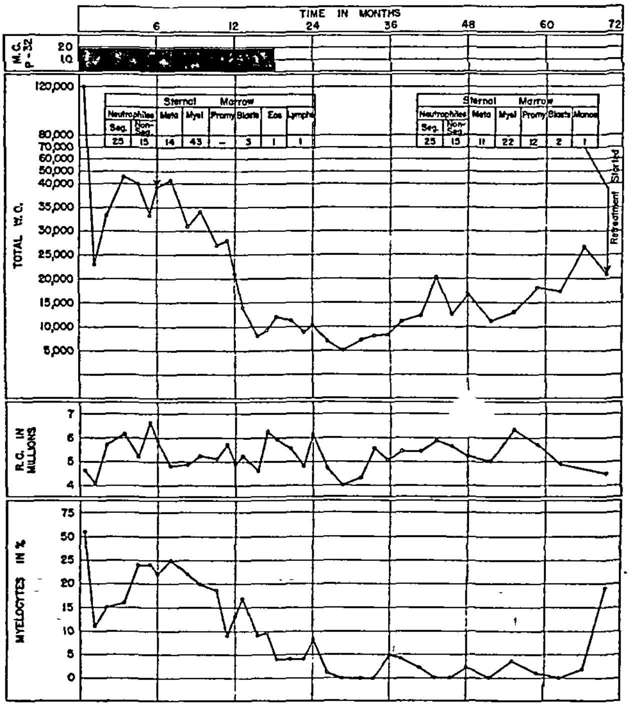

Fig. 7.—P. M., a girl aged 11, who had a long term remission following the initial treatment period of a year and a half. The dosage was small averaging only 1 millicurie a month. This patient has received no P^{32} or other therapy during the past two years, and is now in remission.

Response to Treatment.—In order to illustrate the various types of management and response of these patients to P^{32} several representative charts are presented. Charts 2, 3, 4, 5, 6 and 7 are self explanatory. Chart 8 summarizes the results in all cases, with particular reference to length of life after onset of the disease (3.7 years to date). Most of this life duration is useful life, in which normal activities can be carried on. Another analysis showed that there were no remarkable differences in duration of the disease with various ages of onset, but seemed to indicate that in this series patients showing symptoms in the third decade tend to live longer than those of the other ages.

COMMENT

A study of this series of patients again emphasizes the fact that it is not possible to show any remarkable lengthening of life after irradiation therapy whether it be given by local or total body roentgen radiation, with P^{32} internally, or by a combination of these technics. Final judgment on the relative value of P^{32} must await the evaluation of a much larger series, but it seems clear that no marked lengthening of life is going to result regardless of how the irradiation is given. It is common in the patient with chronic myelogenous leukemia for a picture of acute leukemia to develop terminally, with large numbers of blast cells in the blood smear. At least one third of our patients demonstrated this phenomenon. In order to depress the rapid growth of these young cells one also depresses normal cell production, causing leukopenia, thrombopenia or anemia. Although with P^{32} there is some selective irradiation, nevertheless it is limited. With P^{32} the marrow involved in a leukemic process is sprayed with radiation, but unfortunately such marrow is also the center of normal cell production. Therefore, in the final analysis one must rely on a greater radiosensitivity of leukemic cells, if irradiation is to be beneficial. Even early in the disease this margin of greater radiosensitivity, if present, is not often great, and in animals it has been impossible to demonstrate any greater sensitivity of leukemic over normal cells of the same type.[2c] Consequently, in patients with chronic myelogenous leukemia receiving P^{32}, it is common to see a high platelet count fall to normal or below normal levels, and it is not uncommon to observe a fall in the red cell count. Both of these effects may be the result of the disease or the result of irradiation, and indeed this constitutes one of the great problems in using and evaluating radiation therapy, whether it be local roentgen, spray roentgen or P^{32}. Sternal aspiration of the marrow may assist in deciding, but even in the presence of hyperplastic marrow, one cannot be sure that the platelet, red cell or white cell depression is not due to irradiation. We have tended to use extremely small doses or none in those patients having less than 2,500,000 red cells per cubic millimeter, and instead use local roentgen radiation to the spleen or other areas.

In studying any large series of patients with chronic myelogenous leukemia, one finds cases with extremely short duration of life and others with a relatively long duration of life. As noted in chart 8, that is true of this series, also. In the total series of 129 patients, 21 are alive, and of these, 17 are alive four or more years after onset and 2 are alive nine or more years after onset. In examining these two latter groups, it is difficult to correlate dosage with longevity, although it is true that most of them have responded to relatively small and infrequently administered doses. On the

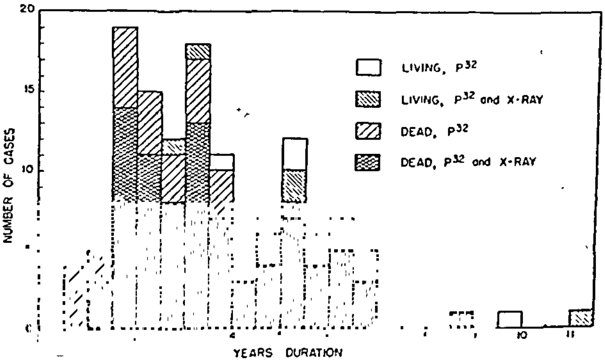

Fig. 8.—Chronic myelogenous leukemia with radiation therapy. The patient living eleven years after onset received only P^{32} until this past year, when some local roentgen radiation to the spleen has been administered. The average duration to date is 3.7 years.

other hand, the larger doses given to some patients have usually been given only after they failed to respond clinically or hematologically to the smaller doses. These patients who are living after several years encourage one, however, to attempt to devise combinations of size and timing of doses of P^{32}, or roentgen rays and P^{32}, which will be most advantageous. It is of interest to note that of late we have tended in some cases to combine local roentgen radiation to the spleen with a background of total body irradiation by intravenous P^{32} in small doses.

It should be emphasized that although this study of irradiated patients demonstrates our inability to control this disease in all instances, nevertheless it does show that the major portion of life duration is useful, and when the follow-up of this series is completed during the coming years, the average duration of life will be somewhat longer than in previously reported series.

In a total of 110 patients dying of leukemia, postmortem examination was obtained in 36. Many patients died in other hospitals, out of contact with us. A number of them had received roentgen treatment prior to death. The postmortem findings were usually those seen in terminal myelogenous leukemia with generalized infiltration of the usual organs and tissues. As illustrated in Figure 4, we have had several patients in which the normal cells (platelets, red cells and normal white cells) have been definitely affected adversely by irradiation, but in the thirty-six postmortem examinations the pathologist felt that the marrow was depressed to the extent of aplastic anemia in but 1 case. However, irradiation can influence the function of cells without obvious morphologic change, so this is not of great significance. Also there were 2 other patients with anemia and leukopenia terminally on whom no postmortem examinations were performed but who had, hematologically, the picture of severe marrow depression. Such marrow depression occurred chiefly in cases which were terminal, in which larger doses were administered as a last resort and combined with transfusions. It would seem that these adverse effects on normal cells with larger doses would clearly rule out the possibility of destroying all leukemic cells by means of irradiation. Again we arrive at the conclusion that palliation is all that can be achieved by radiation, and we must depend more on the resistance of the patient to the disease for the unusually favorable responses. It is of interest to point out that, in this series of patients, some have been given radioactive phosphorus orally or intravenously, intermittently during periods as long as five to ten years, and this is true of the chronic lymphatic series to be reported later. In certain patients the total integrated dose has amounted to as much as 75 millicuries in five years. In none of these has there been evidence of the induction of other neoplasms such as bone tumors. Studies by Brues and co-workers [14] have shown that after large doses of radioactive strontium, osteogenic sarcomas developed in mice. The doses of P^{32} used clinically are probably considerably below the "neoplasm-inducing range of dosage."

At the present time, the two definite advantages of P^{32} would seem to lie in the ease with which it provides generalized irradiation and the lack of any radiation sickness. On these points all workers seem to agree.[15] It is hoped also that further work and the passage of time will show that comfortable life can be prolonged somewhat more than the present figures indicate. Also during the past six years, studies in this laboratory with several radioactive colloids indicate that in certain cases it will be possible to deliver relatively more irradiation to the pathologic tissues as compared to the normal ones.[16] Hahn and Sheppard have recently suggested manganese colloids in a preliminary report.[17] Since there are 21 patients still living, the present figure for average length of life in this series will eventually be somewhat larger.

SUMMARY AND CONCLUSIONS

In a study of 129 patients with chronic myelogenous leukemia treated with P^{32} alone or combined with roentgen rays it was found that comfortable life is prolonged. The somewhat selective irradiation provided by P^{32} has not resulted in any marked improvement in the duration of life in this disease. It does provide a convenient method of giving generalized irradiation, and there is the added advantage of absence of radiation sickness. The fact that 33 patients in this series have lived or are living five or more years after the onset of their symptoms is a reminder that many patients with chronic leukemia have many years of relatively comfortable life, and it is not possible to predict which these will be when they are first seen. Although these studies indicate that P^{32} may be the best therapeutic agent in the treatment of chronic myelogenous leukemia, they also add further emphasis to the need for a search for methods other than irradiation for the ultimate control of this baffling disease.

His Father Was a Blacksmith.—Richard Dewey, one of the most distinguished American psychiatrists of his time, was born the son of a village blacksmith and gristmill owner, in 1845 at Forestville, N. Y. His major contribution to psychiatry was made in 1879 on the assumption of his duties as the first superintendent of the new state hospital at Kankakee, Ill. Here he introduced the so-called "cottage plan," whereby mentally ill patients were no longer indiscriminately herded together but were separated into small groups and housed in separate buildings. This facilitated treatment and secured for the patients many of the advantages of community life.

Among Dr. Dewey's literary activities may be mentioned his collaboration with five other American and Canadian psychiatrists in the writing of the monumental four volume history, "The Institutional Care of the Insane in the United States and Canada," which was published in 1916-1917, and his editorship from 1894 to 1897 of the *American Journal of Insanity* (now the *American Journal of Psychiatry*).—Rosen, George, and Caspari-Rosen, Beate: 400 Years of a Doctor's Life, New York, Schuman's, 1947.

CONGENITAL ANOMALIES OF THE GALLBLADDER

BRUCE C. LOCKWOOD, M.D.
Detroit

Until cholecystography became a common diagnostic procedure developmental defects of the gallbladder were considered to be rare anatomic curiosities and were reported only by anatomists. They are now not uncommonly found. Their clinical significance has been disputed.

Considering the embryologic development of the region, one wonders that such defects are not more frequent. The biliary tract arises in the human embryo as a diverticulum from the ventral surface of the foregut just cranial to the yolk sac. Two solid buds of cells form the right and left lobes of the liver while the original elongated diverticulum forms the hepatic and common ducts. The gallbladder develops as a smaller bud of cells off this same diverticulum, and when the embryo is 15 mm. long it is represented as a long solid tube lying in its hepatic fossa. Later it develops a lumen by a process described as vacuolization, which takes place simultaneously in different parts of the then solid gallbladder bud. Fusion of these vacuoles forms the normal gallbladder cavity. Irregularity in the formation and fusion of these vacuoles accounts for deformities such as aberrant valves of Heister, strictures, hourglass shape or absence of the ducts or gallbladder, while a splitting of the bud may cause a double or a bilobate gallbladder or a diverticulum. Abnormalities in the development of the original diverticulum cause defects of the bile duct and of the liver.[1]

TABLE 1.—*Classification of Congenital Anomalies of the Gallbladder and Ducts*

1—Anomalies of the form of the gallbladder
    Phrygian cap, liberty cap or folded fundus type
    Fish hook type
    Partitioned type
    Bilobed
    Diverticulum
2—Anomalies of the number
    Absent
    Rudimentary
    Double
3—Anomalies of the position of the gallbladder
    Intrahepatic
    Floating or ptotic
    Left sided
        On under surface of left lobe
        Situs transversus
4—Anomalies of cystic duct
    Absent
    Stricture
    Reduplication
    Abnormal termination into stomach
5—Anomalies of hepatic and common ducts
    Absence
    Stricture
    Reduplication
    Abnormal termination into stomach
6—Anomalies of hepatic and cystic arteries
    Double cystic artery
    Abnormal relation of hepatic artery to cystic duct

In table 1 is shown a classification of the types of malformations of the gallbladder and ducts which have been found to occur.

The most common anomaly of the biliary tract is the Phrygian cap or the folded fundus type of gallbladder. This condition is due to a defect in the vacuolization of the solid gallbladder bud, in which a partial septum or septums remain in the lumen. It is this type of deformity with which this report is chiefly concerned.

Cholecystography is the method most likely to reveal such congenital deformities. I am convinced that in most cases the deformity has been overlooked by surgeons, because in the usual operative procedure the application of forceps on the gallbladder with traction obliterates the external appearance of the deformity. Furthermore, some of these defects are almost totally concealed inside the gallbladder, and the external appearance is fairly normal. The mind of the surgeon is usually chiefly occupied with the technical procedure on hand. It is also probable that most of these deformities are overlooked in the pathologic laboratory because the specimen is usually handled by a technician interested only in excising a small piece for microscopic examination. The condition is also evidently missed or not reported at autopsies.

TABLE 2.—*Data on Forty-One Patients Showing Cholecystographic Evidence of Congenital Anomaly of the Gallbladder*

Total number of cholecystograms for a six year period—1,464
Number showing anomalies of the gallbladder—41, or 2.8 per cent
    Males—13, or 32 per cent; females—28, or 68 per cent
    Average age—43
Dye concentration—Normal in 14, or 34 per cent, and below normal in 27, or 66 per cent
Fat response—Normal in 11, or 27 per cent, and below normal in 30, or 73 per cent
Number showing stones—6, or 14 per cent
Patients in whom symptoms were considered caused by the gallbladder—13, or 32 per cent
Patients who originally had normal function of the gallbladder but in whom definite gallbladder trouble later developed—8, or 19 per cent
Total number having gallbladder trouble to date—21, or 51 per cent
Number operated on to date—10, or 24 per cent

Attention was first called to the folded fundus type of gallbladder by the anatomist Bartel[2] in Germany, who in 1916 had collected forty-three such specimens at autopsy. He gave it the name of "Phrygian cap," referring to the headgear worn by the people of Phrygia, an ancient country of Asia. A conical cap with the top turned forward was then an emblem of liberty or republicanism. The goddess of liberty is still occasionally pictured wearing such a cap.

After the discovery of the Graham-Cole[3] dye method of roentgen examination of the gallbladder in 1925 a number of cases were found and reported. Most surgeons considered the condition to be a congenital pathologic one of definite clinical significance and an indication for cholecystectomy.[4] Boyden[1] in 1935, however, reported a careful study of the condition from an embryologic and anatomic standpoint and concluded that it is a congenital variation probably of no significance. He reported a series of one hundred and sixty-five cholecystographic studies on normal persons in which a Phrygian cap deformity was found in 3.6 per cent.

Meyer, Carter and Meeker[5] in 1937 also studied the condition. They found that in a series of one

hundred gallbladders removed at operation for cholecystitis the deformity was seen in 6 per cent. They reviewed one thousand routine cholecystograms and found that in about 4 per cent septal divisions corresponding to the Phrygian cap deformity were seen.

In table 2 is shown a résumé of the pertinent data regarding the group of 41 patients who showed definite cholecystographic evidence of congenital deformities of the gallbladder. These patients were among a series of 1,464 office patients who because of gastrointestinal symptoms were subjected to routine roentgen examination of the gastrointestinal tract and of the gallbladder as well as to clinical and laboratory examination. It will be noted that the incidence of deformities in this series is 2.8 per cent, a figure slightly below that reported by Boyden and by Meyer, Carter and Meeker. The ratio of females to males was about 2 to 1. The average age was 43 years. The response to dye concentration tests and fat meal tests was found to be below normal in over two thirds of the cases, and stones were found in 14 per cent.

In 32 per cent of this series it was originally considered, after careful complete examination, that the patients' symptoms were due to gallbladder disease. In another 19 per cent symptoms and roentgenologic signs of gallbladder trouble subsequently developed. Thus 51 per cent of this series of 41 patients showing cholecystographic evidence of congenital anomalies of the gallbladder also had definite cholecystitis, with 14 per cent exhibiting calculi.

There are other forms of abnormal development of the biliary tract, as shown in table 1. It has been estimated that about 10 per cent of human beings have some anomaly of the biliary tract.[6] Total absence of the gallbladder is rare, as is rudimentary gallbladder, the incidence at autopsy being about 0.03 per cent.[7] Double gallbladder is also rare; Boyden[8] found it in only 5 of 19,000 subjects. Complete intrahepatic gallbladder is rare although a gallbladder with a fundus partially buried in the hepatic structure is occasionally encountered. An instance of this is included in the series here reported. Low, pelvic or ptotic gallbladders are most common. Gallbladders situated on the under surface of the left lobe of the liver, though rare, have been reported by several observers.[9]

Congenital variations in the bile ducts and in blood vessels are not infrequently encountered at operation,[10] and every surgeon should be alert to the possibility of their presence and trained to cope with their existence.

SUMMARY AND CONCLUSIONS

1. This study represents a survey of consecutive cholecystographic studies on 1,464 patients, in 41, or 2.8 per cent, of whom there was evidence of congenital deformity.

2. In about 70 per cent of this group of 41 patients, observed over a period of six months to six years, there was suggestive evidence of disease of the gallbladder, and in 51 per cent there was definite evidence. Calculi occurred in 14 per cent. Operation was necessary in 24 per cent.

3. Congenital anomalies of the gallbladder interfere with its normal function in a great majority of cases and are therefore of definite clinical significance.

4. For patients with such anomalies a medical routine to promote normal function of the liver and gallbladder and especially to avoid gallbladder stasis should be followed.

5. Surgical treatment is indicated for calculi and for a nonfunctioning gallbladder with persistent symptoms.

PRIMARY CARCINOMA OF THE SEMINAL VESICLES

Differentiation From Extrarectal and Rectal Carcinoma and Comparative Study

LOWRAIN E. McCREA
Philadelphia

Primary carcinoma of the seminal vesicles and tumors of the rectal shelf or of Blumer's shelf may offer confusion in the differential diagnosis. The relative frequency with which extrarectal metastatic deposits and primary extrarectal growths are encountered is a subject that has received little attention from the profession until recent years.

The differential diagnosis of the two conditions is highly important and constitutes the primary step in affording relief, if possible, to the patients suffering from them. Extrarectal carcinoma is frequently confused with primary rectal carcinoma, although a wide chasm of symptoms and physical findings exists between the two conditions. Because of their importance clinically and because of their physical properties, considerable attention has been focused on rectal tumors and on Blumer's shelf tumors by the proctologic surgeons. There is little in the literature on primary carcinoma of the seminal vesicles. The site, contour and palpable qualities of extrarectal metastatic malignant growths and of primary carcinoma of the seminal vesicles are similar and frequently offer considerable difficulty in differentiation. So similar are these lesions that it is frequently impossible to differentiate between them unless biopsy is done.

Extrarectal metastatic malignant growths are observed in the male in the rectovesical pouch or cul-de-sac. The rectovesical pouch is formed as the peritoneum is reflected from the bladder onto the upper two thirds of the anterior and lateral aspects of the rectum. The pouch thus formed descends to a point within 1 cm. of the base of the prostate. When the rectum is filled or the bladder distended, two peritoneal folds may be found passing from the lateral walls of the bladder to the rectum. These peritoneal folds or rectovesical ligaments form the lateral boundaries of the pelvic peritoneal or rectovesical cul-de-sac. Metastatic deposits of appreciable size in the cul-de-sac produce a ledge known as the rectal shelf which is palpated just superior to the prostate, which is the normal site of the seminal vesicles. Attention was first called to extrarectal tumors in 1895

Read before the Section on Urology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

by Strauss,[1] who reported a case of gastric carcinoma with metastasis to the pouch of Douglas. Blumer in 1909[2] so classically described extrarectal metastatic lesions that they are spoken of as Blumer's shelf tumors. Bacon in 1939,[3] in reviewing the literature, found 41 cases and reported 17 of his own. In his series Bacon[4] observed that the primary growths were found most frequently in the stomach. Some of the patients were without gastric symptoms, but symptoms were produced by the metastatic growths. Buie[5] in 1941 reviewed 254 cases of extrarectal tumors observed in a five year period and found in 63 per cent of his cases that the cause of the extrarectal mass or rectal shelf varied. He observed that the primary growths occurred as carcinoma of the stomach in 30 cases, endometriosis and adenomyosis in 30 cases, carcinoma of the sigmoid in 26 cases, diverticulitis in 26 cases, pelvic inflammatory disease in 22 cases, carcinoma of the ovary in 14 cases and carcinoma of the prostate in 13 cases. In the remaining 37 per cent of his cases there were a great variety of pathologic processes including carcinoma of the breast, giant cell tumor of the bone, lymphosarcoma, regional ileitis, carcinoma of the cervix, cyst of the ovary, retroversion of the uterus, ruptured appendix, perforated peptic ulcer, carcinoma of the seminal vesicles, hypertrophy of the prostate, epithelioma of the bladder and carcinoma and sarcoma of the rectovaginal septum. It is noteworthy that in Buie's series the most common cause of an extrarectal mass or of a tumor of the rectal shelf among men were lesions of the gastrointestinal tract, while lesions of the genital system were observed as the common cause of such tumors in women.

An infiltrative carcinomatous mass palpated in the area usually considered as the rectal shelf may readily be mistaken for a primary tumor of the seminal vesicles. It has been repeatedly shown that tumors of the rectal shelf are metastatic lesions and that the greatest incidence of occurrence is found in carcinoma of the stomach. It is frequent that patients with tumors of the rectal shelf present a history of gastric complaints while persons with primary carcinoma of the seminal vesicles frequently present a history of urinary difficulty and hematuria. It is considered that the greatest diagnostic point of differentiation between extrarectal and rectal carcinoma is the mobility of the rectal mucosa over the mass in extrarectal tumors. It has been shown that such tumors not infrequently invade the rectal mucosa and become fixed tumors. Primary carcinoma of the seminal vesicles belongs to the category of extrarectal tumors because of its site and palpable qualities. The occurrence of this tumor, although uncommon, is not believed to be as rare as the sparsity of the reported cases in the literature would suggest. It is further believed that many of the tumors diagnosed as Blumer's shelf tumors were in reality primary carcinomas of the seminal vesicles. The first case of primary carcinoma of the seminal vesicles to be reported was that of Berger[6] in 1871. In 1942, in a review of the literature,[7] I found 19 cases and reported 2 of my own. Since that time mention has been made in the literature of 2 more cases by Morales, Alcalde, Obrador and Perrin.[8] Another proved case is herein reported, bringing the total number of reported cases of primary carcinoma of the seminal vesicles to 24. In all 3 cases personally observed three symptoms were constant, namely, frequency of urination, difficulty of urination and hematuria. In 2 of the cases catheterization was necessary, while in the third case cystotomy was done to relieve urinary difficulty. The hematuria as observed was not frank bleeding but rather was a mixture of urine, blood and blood clots together with masses of cellular debris.

CASE 3.—H. M., a white man, 38 years of age, was admitted to the hospital on Feb. 9, 1946, in a state of acute urinary retention. There was a history of a two week period of difficulty and frequency of urination and hematuria. Rectal examination revealed a large mass above the prostate. A definite sulcus existed between the prostate and the irregularly shaped, elastic, fixed mass. The rectal mucosa was smooth and freely movable. Cystoscopic examination revealed a markedly elevated trigone. The ureteral orifices were normal in contour but widely separated. A craggy, irregularly shaped tumor mass was visible on the trigone. The blood urea nitrogen was 47.6 mg. per hundred cubic centimeters.

On March 5 biopsy was performed, and the report was as follows: "The specimen consists of bits of bowel wall lined by glandular mucosa which is ulcerated at various points and engaged in a marked inflammatory reaction. Ill formed glands are seen. In addition there are darker-staining, less differentiated cells. The same picture can be found in the wall beneath a benign mucosa."

On March 10 cystotomy drainage was instituted, and a biopsy of material from the bladder wall resulted in the following report: "Section of this piece of tissue shows it to consist of a more or less solid mass of undifferentiated tumor cells showing unquestionable malignant change (fig. 1). In some regions there is a tendency for papillary proliferation. Necrosis is prominent. The cells are not characteristic of those which arise in the acini of the prostate. It is impossible to say that this is not rising in the transitional epithelium of bladder mucosa. The structure of the cells, however, is compatible with a malignant tumor of the seminal vesicles. The diagnosis is carcinoma, primary in the seminal vesicles."

On April 14 the patient died. Autopsy revealed generalized metastasis.

The two following cases were originally reported in 1942 but are reviewed here for comparison.

CASE 1.—W. L. a white man 34 years of age, complained of an attack of hematuria and an intermittent dull pain over the kidneys and the bladder region three weeks before he was first observed, on Jan. 20, 1940. When first seen the voided urine was cloudy but not bloody in appearance. Microscopically, 30 to 40 red blood cells and numerous clumps of leukocytes per high power field were present. On rectal examination a hard indurated fixed mass was palpable above the prostate. The patient refused to undergo further examination.

On Sept. 4, 1941, the patient complained of frequency of urination, dysuria, nocturia and hematuria. Cystoscopic examination revealed a greatly elevated bladder floor. The mucosa was somewhat congested and presented a coarsely granular appearance. Extensive areas of bullous edema which obscured the ureteral orifices were present.

On October 7 material was taken for biopsy, with the patient under spinal anesthesia. A specimen was taken from the bladder and one from the rectum. The pathologic report was as follows: "The biopsy of the bladder reveals mild hyperplasia of the mucosal covering, with retial formation. The cells making up this layer have been cut in such a fashion that they appear to group themselves around a central space. They are adult in type and orderly in arrangement and show no attempt at invasion. The subepithelial layer reveals edema, congestion and sparse plasma cell infiltration. There is a focal aggregation of lymphocytes in one area. The remainder of the wall exhibits fibrosis and vascular thickening (fig. 2). The specimen labeled 'rectum' presents a fibrofatty and muscular tissue in which are caught large nodules of acinar structures which have the arrangement and branching effect of seminal vesicle tissue. The lining cells are tall and cuboidal and present variation in size, shape and staining quality. There are macular areas of recent hemorrhage. No mucosal covering is visualized. From the cytologic detail and the arrangement of the neoplastic cells, we feel that this lesion represents a low grade adenocarcinoma primary in the seminal vesicles. The diagnosis is adenocarcinoma, grade 2, which is primary in the seminal vesicles, and chronic cystitis."

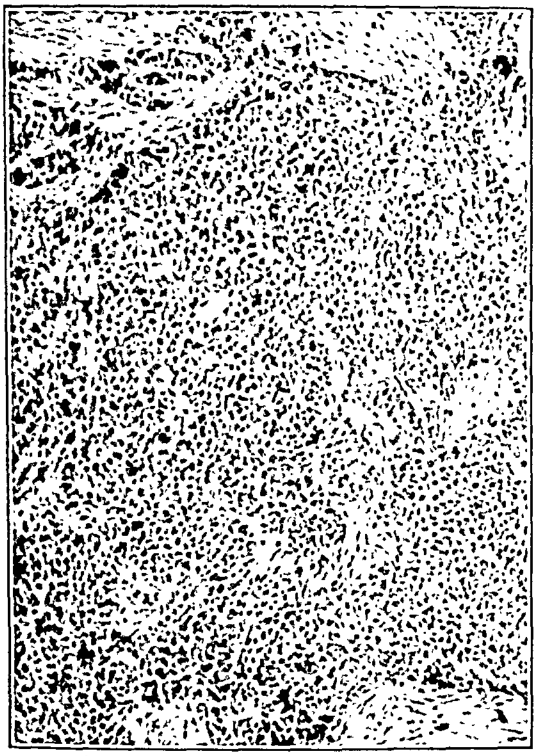

Fig. 1.—Photomicrograph showing tumor consisting of relatively undifferentiated solid masses of cells. Note the large-sized nuclei with prominent chromatin and also the numerous mitotic figures. Little stroma is seen.

Because of inoperability, the patient was subjected to roentgen therapy.

On May 21, 1942, a large necrotic mass of tissue was passed through the urethra, which was followed by increased frequency of urination, with smarting and burning.

On May 22 cystoscopy revealed extensive bullous edema and an infiltrative mass which extended across the trigone.

By August 2 there was considerable loss of weight, and the patient complained of loss of sleep due to considerable frequency of urination and to constant dull pain in the perineum. Rectal examination revealed diminution in the size of the indurated fixed mass above the prostate.

On December 18 the patient was admitted to the hospital in a uremic state, and he died shortly after. Autopsy revealed a large tumor mass involving the seminal vesicles and infiltrating the trigone of the bladder (fig. 3).

Case 2.—W. M., a white man 52 years of age, was admitted to the hospital on Aug. 18, 1941. The history revealed marked loss of weight during the preceding four months, increased bowel movements (ten to twelve watery stools a day) and difficult urination. Rectal examination revealed a mass beginning about 2.5 cm. above the anterior anal margin, extending backward and compressing the rectum against the sacrum. The examining finger could be introduced beyond the mass. The mass was irregular in shape, elastic but definitely fixed and covered by smooth mucous membrane. The cystoscope was introduced with difficulty because of the extreme angle necessary to allow the beak of the instrument to pass over the markedly elevated prostatic urethra and trigone. The bladder mucosa was normal in appearance. The ureteral orifices were normally placed and readily visualized. There was no evidence of tumorous growth within the bladder.

The report of a biopsy of rectal tissue was as follows: "There is one small piece of bowel mucosa which shows chronic inflammatory changes. Deep in this there are fragments of necrotic granulation tissue and a few smaller pieces of papillary adenocarcinoma. The epithelial cells are tall and sometimes goblet shaped. They are apparently mucin secreting. The grade of malignancy is not particularly high. The question of primary source arises. Since this tumor is papillary it probably does not arise from the prostate, and since it is of an acinar pattern it probably does not arise in the bladder mucosa. Since the rectal mucosa appears to be free of tumor we must assume that the tumor springs from the seminal vesicles. The diagnosis is papillary adenocarcinoma, grade 2, of the seminal vesicles."

On August 21 colostomy was done by Dr. Harry E. Bacon because of an imminent total obstruction of the bowel. At the time of operation a mass approximately the size of a grapefruit was noted. The mass practically filled the pelvis. The lower limit could not be determined, but it extended well below the promontory of the sacrum. It was causing almost total obstruction to the sigmoid and was fixed to the bladder.

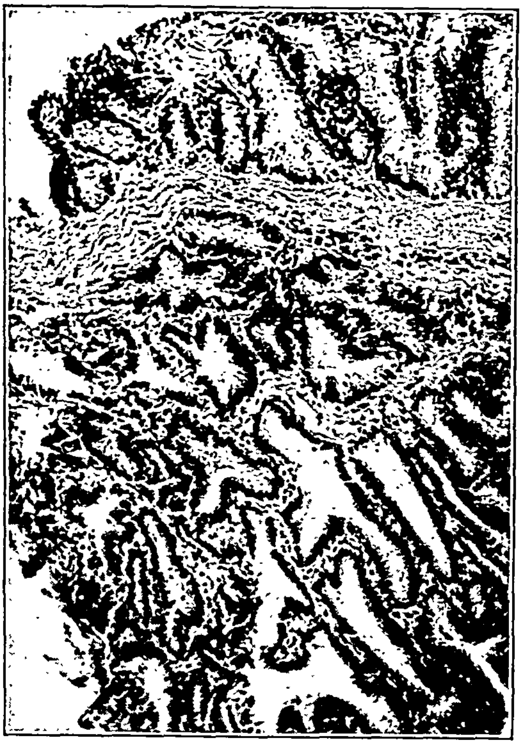

Fig. 2.—Photomicrograph showing acinar structures which have the arrangement and branching effect of the seminal vesicles. The living cells are cuboidal and show definite variations in size, shape and staining qualities.

On Jan. 12, 1942, the patient succumbed, having continued his downward course after the colostomy. Autopsy was not permitted.

INTERPRETATIONS OF PHYSICAL FINDINGS IN CARCINOMA OF THE SEMINAL VESICLES

Cystoscopy in all 3 instances revealed a markedly elevated trigone and floor of the bladder. In 2 instances a distinct craggy mass infiltrating that area could be seen. Rectal examination revealed a mass above the prostate, with the production of a rectal shelf. In 1 instance the mass was so large that mechanical obstruction to the lower bowel was evident which required colostomy. The rectal mucosa was not adherent in any of the cases but moved freely in all directions. The prostate was distinctly palpable as a separate organ and was not involved in the mass, and a distinct but shallow sulcus was readily palpated between the prostate and the mass lying superiorly. In primary carcinoma of the rectum the mucosa is fixed and the mass frequently bleeds during or after palpation. It is usual that bloody stools have been apparent for a period of time, and it is usual that such bleeding prompted examination. Such rectal bleeding does not occur with Blumer's shelf tumors or with primary carcinoma of the seminal vesicles unless invasion of the rectal mucosa has occurred. Similar findings have been made on palpation in instances of metastatic tumors, extrarectal tumors or Blumer's shelf tumors. It then becomes obvious that persons presenting such lesions or masses palpable in the rectum should receive the benefit of considerable study. Extrarectal or rectal shelf metastatic tumors have been shown to accompany distant primary tumors. It is usual that primary tumors of the rectum and extrarectal tumors do not produce urinary symptoms, but such symptoms are considered to be constant in primary carcinoma of the seminal vesicles. The rectal mucosa is generally intact and freely movable over the rectal shelf or over the carcinoma of the seminal vesicles. This is the most important feature distinguishing such tumors from rectal carcinoma. Carcinoma of the seminal vesicles and tumors of the rectal shelf do not bleed on examination, whereas in carcinoma of the rectum bleeding on examination has been shown to be constant.

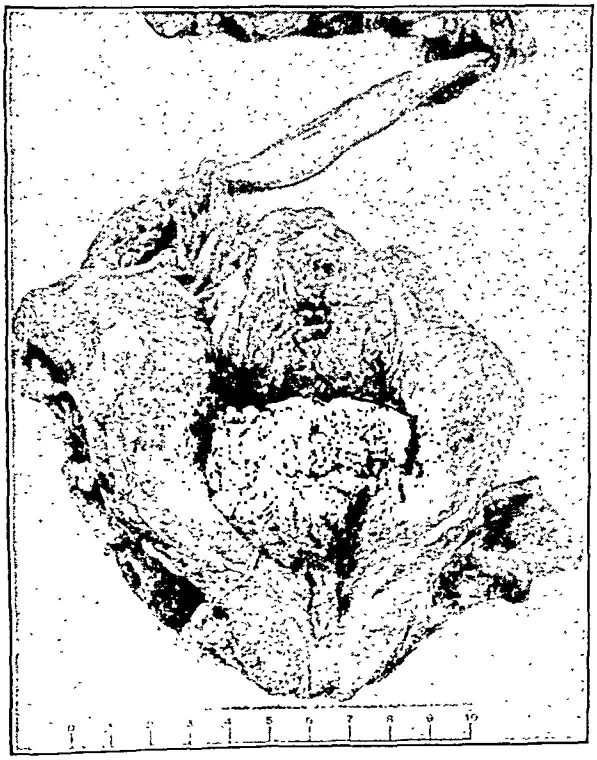

Fig. 3.—Photograph of bladder removed at autopsy. A distinct craggy mass may be seen on the floor of the bladder. A greatly dilated right ureter may also be seen.

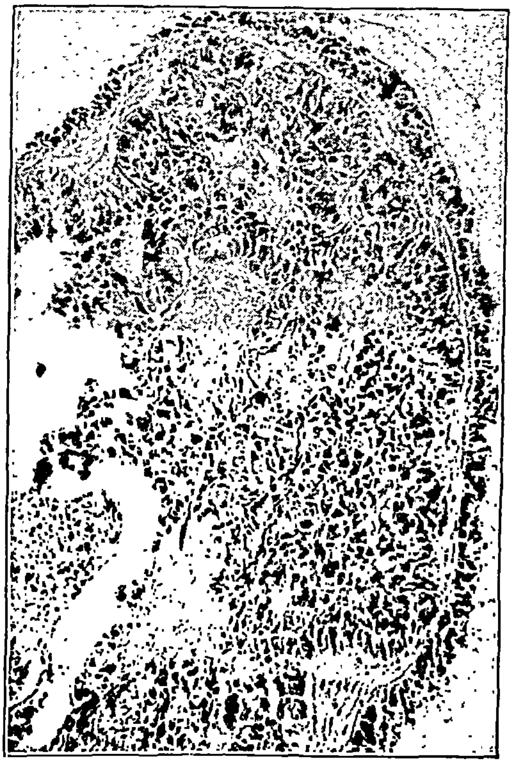

Fig. 4.—Photomicrograph showing acinar pattern. The epithelial cells are tall and sometimes goblet shaped.

TREATMENT

The treatment of primary carcinoma of the seminal vesicles is obviously unsatisfactory. Because of the nature of these organs and their anatomic position, widespread infiltration is present by the time symptoms are produced and a diagnosis can be made. Such infiltration is usually so extensive that excision is impossible. To date palliative procedures only have been considered, and with such procedures the end result is inevitable.

SUMMARY

1. The differential diagnosis of primary carcinoma of the seminal vesicles, primary carcinoma of the rectum and Blumer's shelf tumors has been reviewed. Differentiation may be difficult and is best made by biopsy.

2. Primary carcinoma of the seminal vesicles is rare, but it is believed that it is not as rare as the sparsity of the literature on the subject would suggest. To date 23 cases have been reported in the literature. To this number 1 has been added, bringing the total to 24 cases. Of this total, in only 10, including the case just reported, has the disease been proved histologically.

3. The cardinal symptoms of primary carcinoma of the seminal vesicles are frequency and difficulty of urination and hematuria associated with the rectal mass palpable above the prostate.

4. The treatment of primary carcinoma of the seminal vesicles is unsatisfactory. Excision is impossible, and only palliative measures may be considered.

1930 Chestnut Street, Philadelphia.

Special Article

CUTANEOUS CANCER

HENRY E. MICHELSON, M.D.
Minneapolis

This article is the eleventh of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

The questions that remain to be answered about cutaneous cancer today are essentially those that pertain to all forms of cancer, but the problem of cutaneous cancer offers more possibility of control, if not solution, because of the visibility and accessibility of the lesions. Early recognition and total eradication are the goal of the practitioner. Predisposing factors and the actual cause of the disease remain the problem of the research program.

Although cutaneous cancer has long been recognized and has been described in the earliest medical literature it still is the cause of irreparable damage, unsightly deformity and even death. Progress in treatment has been made largely through the application of some forms of radiation therapy and by modern surgery with plastic repair.

As a large percentage of cutaneous cancer occurs on the exposed parts of the body, there should be little difficulty in clinical diagnosis. The ease with which specimens for microscopic study can be obtained makes positive diagnosis easy. Despite this, deplorable numbers of early cutaneous cancers are missed, either because practitioners are not suspicious of the condition with which they are dealing or because they fail to persevere until all possibility of new growth in a "trivial" or "benign-appearing" lesion has been ruled out. Delay means extension of malignant growth; too often the trivial lesions become an inoperable cancer because of the mistaken policy of watchful waiting.

The classification of cutaneous cancers is not so important diagnostically as it is therapeutically. Hence the educational theme should be to emphasize the need of looking on every localized cutaneous growth, regardless of its size or duration, as a potential cancer and of not being satisfied until an accurate microscopic diagnosis has been secured. Performance of a biopsy in every such growth is imperative, even though at times the circumstances may allow a purely clinical diagnosis. I do not believe that one should emphasize the need for differentiating basal cell from squamous cell cancers of the skin as much as one should stress the great need for recognizing the characteristics of cutaneous growths that are diagnostically significant of tumor growth. The delays in positive diagnosis and the errors in judgment that have allowed comparatively simple lesions to become serious ones are usually due to the failure of the first physician consulted to accumulate the necessary evidence on which to base a positive diagnosis. The following points are worthy of consideration in every patient who presents a suspicious cutaneous lesion.

AGE OF THE PATIENT

Cutaneous cancer may occur at any age. The youth of the patient never precludes the possibility of a lesion's being cancerous. It is true that the majority of such lesions occur in persons past 50, but they may occur even in early youth.

AGE OF THE GROWTH

Age of the growth is very important because cutaneous cancers may remain stationary for long periods. It is a particularly unfortunate misconception that a lesion which has been present for a number of years, has not progressed and has caused no discomfort cannot be very dangerous. Many lesions which on microscopic examination are proved to be of a highly malignant character may have been present for many years but remained small and showed little activity for reasons that we do not understand; nevertheless they will sooner or later invade the surrounding tissue or even metastasize and become grave therapeutic problems. One should be especially careful not to be misled by a small stationary growth, but always investigate it as thoroughly as one would a more destructive one.

SIZE OF THE GROWTH

With the exception of the malignant melanoma, the smaller any cancer is the better the prognosis. Fortunate is the patient whose minute cutaneous cancer has been recognized and properly treated while it was still small. If the growth has not been completely eradicated it is almost certain to become active at some future time. One should never merely watch a tiny lesion because it is small and is not causing trouble. This is the ideal time for treatment.

MORPHOLOGIC TYPE OF LESION

It is of the utmost importance to distinguish the morphologic type of lesion to be dealt with. The surface plane of the skin is the boundary line. Lesions which grow upward, that is, rise above the skin surface, as a rule are easier to manage than those whose direction of growth is either lateral, downward or both. The appearance of the base of the lesion gives valuable information. Lesions having a constricted base that tend to become pedunculated are usually more amenable to treatment. Those with a broad sessile base, no matter how elevated the lesion itself, still belong to the more tractable group, but when growth is downward and laterally the lesion is penetrating into less accessible and more dangerous ground, with treatment more difficult and prognosis often grave. Infiltration and ulceration show extension and above all else should impress the examiner that he cannot by microscopic means accurately or completely outline the boundaries of the growth. Undoubtedly one of the chief reasons for failure in radiation treatment is the inability to visualize the projections of the growth, especially in infiltrating lesions. In this type of growth, it is well to extend the treatment beyond the visible involved area. So-called recurrences may often be the result of growth extensions that were present but had not been suspected and hence not treated. One of the crying needs for

---

From the Division of Dermatology, University of Minnesota, H. E. Michelson, M.D., Director.

successful treatment of cutaneous cancer is a means for visualizing and outlining the entire growth. It is to be hoped that research directed toward this end will be furthered. A dye, an electronic method or a refined roentgen technic which would give the therapeutist an accurate lateral and depth outline of a cutaneous cancer would be of immeasurable value in facilitating treatment and preventing subsequent *trouble.*

LOCATION OF THE LESION

Merely noting that a lesion is in a certain area is not sufficient. The experienced physician in this line of work realizes that certain anatomic locations offer a much more serious problem than others. Recalling the minute anatomy of the part is essential. The blood supply, the lymphatic drainage, the proximity to inaccessible cavities and the character of the tissue must all be taken into consideration.

As a rule lesions occurring in soft movable parts such as the center of the cheek are much easier to handle than lesions occurring in parts that are tightly stretched over the underlying tissues such as the tip of the nose, the chin and similar areas. If a growth is freely movable and can be manipulated easily it allows a varied therapeutic attack. Total excision is possible without deformity, and such a lesion gives more reassurance of successful treatment. Lesions occurring where bone or cartilage is just below the skin always cause apprehension. If such a lesion is at the entrance of the nasal, auditory or orbital cavity the problem is that much more complex; more drastic means are necessary to effect total destruction, for recurrence would probably be in an inaccessible area. Proximity to node-bearing areas must also be considered, particularly in *growths occurring in the integument whose lymphatics* drain toward the inguinal nodes. Cancers of the circumanal, perineal, genital and pubic regions should always be most carefully evaluated because of this fact. Extension of cancer into the inguinal nodes is a serious complication because of the difficulty of complete removal by dissection.

Although a large percentage of cutaneous cancers occur on the face, no area is immune and every location offers its own peculiar problem. The back of the hand, where cancers occur quite frequently, might be mentioned; here the anatomic structure offers many obstacles to efficient therapy.

RATE OF GROWTH

The more rapid the growth of a cutaneous cancer the more grave the prognosis. Although the microscopic diagnosis may not suggest a very serious type of cancer, the fact that the surrounding tissues are not offering an effective barrier to extension is most *important.* Conversely a sluggish, slowly growing lesion denotes good tissue resistance and that the area of new growth is well confined.

DEVELOPMENT

Since nothing is known of the etiology and pathogenesis or of the true biology of most cancers of the skin, it is impossible to discuss predisposing factors or why certain areas of the skin are more often the seat of cancer than others. Very early lesions are not often seen in practice, but enough of such growths have been *studied* so that we know their visible developmental changes. Almost all cutaneous cancers which do not develop in a preexisting lesion begin as a small globular elevation, which has the appearance of a minute multilocular cyst. As growth proceeds, the lesion extends both peripherally and in height, and after a certain size has been attained has the appearance of a small broad-based dome, rather translucent, overlaced with small blood vessels. If the growth extends laterally *and not downward the lesion may not change in appear*ance, but usually extension is in all directions, and in this case the nutrition of the central portion is soon interfered with and the center sinks, necroses or ulcerates. If there is considerable secretion a crust forms and the lesion then becomes a crusted ulcer. Subsequent progress depends on the anatomic character of the part involved, on the rapidity of growth and on the amount of sclerosis that the tissues can produce. At first the lesion is round, but as growth is not uniform it soon becomes irregular in outline. This description applies to most cancers of the skin irrespective of their microscopic appearance; hence the clinician must not expect only a certain type of morphologic growth to be cancerous, but must realize that a cancerous lesion may vary from a small translucent globule to a large crusted ulcer. From the morphologic appearance an experienced observer may with a fair degree of certainty predict the histologic features, but accurate classification can only be made microscopically. Classification of such tumors must be based on their histology, for a clinical classification is at present impossible.

PRECANCEROUS LESIONS

Precancerous lesions constitute a group of cutaneous lesions difficult to define and more difficult to recognize as such. We call precancerous those pathologic changes in tissue which without being cancerous show the tendency sooner or later to develop into actual cancer. Unfortunately many excellent studies of this group of cutaneous lesions disappointingly did not throw much light on the beginning of cell cancerization. Neither did study of precancerous lesions prove that one type of lesion always metamorphosed into a certain type of cancer. The importance of recognizing precancerous lesions in the skin is prophylactic because it may be said that development of severe cancer and death traced to cancer of the skin would be tremendously decreased if all precancerous lesions were properly diagnosed and *destroyed. It should be noted, however that there are* many so-called precancerous lesions which change so *slowly that a cancer does not develop from them within* the patient's lifetime; nevertheless one is unable to foretell and therefore from a practical point of view all fixed keratoses may be considered precancerous, although a statistical study reveals that so-called senile keratosis is much more important than seborrhoeic keratosis. However, complete removal of both types is the only safe procedure and should be unhesitatingly advocated; although differentiation of these two types of keratoses is histologic, microscopic study of all keratoses before treatment need not be done; however, if keratosis recurs at the same site after removal by a reliable method, microscopic study should be done before retreatment.

Areas harboring chronic inflammation, such as plaques of lupus vulgaris, discoid lupus erythematosus, chronic roentgen dermatitis and even stasis ulcers, may be broadly considered precancerous.

Attention is called to the fact that a change in the type of inflammation or in the morphology of the diseases just mentioned should immediately arouse suspicion and call for microscopic study. For the general practitioner I do not believe that it is necessary to distinguish such rare dermatoses, as for example Bowen's disease, which may be classified with the keratoses and with Paget's disease. Here again the emphasis should be on the danger which is potential in any fixed, persistent and irresponsive cutaneous lesion. In such a lesion regardless of its more minute characteristics, cancer must be placed high on the list of possibilities and can be excluded only by the lesion's being proved free from cancerous changes. This can only be ascertained by microscopic study.

BASIC TYPES

Basic types of cancers of the skin are usually divided roughly into basal cell and squamous cell types, and these two basic types are deemed sufficient for a brief practical discussion. It is not proposed in this communication to review the various rare cancers which arise from glandular tissue and other infrequent types and combined forms. Therapy as well as prognosis of cutaneous cancer is based in general on the clinical appraisal plus the results of biopsy. A quick decision can usually be made from such findings; extended study demands serial sections and is not practical in everyday practice.

The basal cell cancer is the most frequent and the least malignant of the cancers of the skin. The lesions are strictly confined and do not metastasize. They have certain clinical characteristics, but these are not as reliable diagnostically as their microscopic features, which are rather typical and uniform. I have noted a tendency of practitioners to make a clinical diagnosis of basal cell cancer with the implication that the lesion is benign, even trivial. I am much opposed to diagnosing the type of cancer by macroscopic examination alone and believe that a great many failures of treatment are due to this practice. It should be emphasized that the type of cancer cannot be accurately diagnosed without microscopic aid. Pedagogically it would be far better if no effort were made to differentiate between types and diagnosis were confined to the over-all term "cancer of the skin." The squamous cell cancer may have the same morphologic appearance as a basal cell cancer. It cannot be diagnosed as such any more than the basal cell type can by inspection, but it is even more important to demand diagnosis by microscope, for the squamous cell cancer is much more resistant to radiation treatment and furthermore may metastasize to the adjacent nodes or glands.

Most cancers of the skin occur on exposed parts, a large percentage being on the face, neck, ears and forehead. They occur on the hands and a lesser number on the trunk and in various other locations. It is more important to evaluate the precise anatomic location than the region.

On certain areas of the integument or its adjacent mucous membrane if involved a uniform type of cancer seems to develop. This is particularly true of the lip, dorsum of the hand and the external genitals. In these areas basal cell cancer occurs very infrequently. On the other hand, there is no area of the body about which it may be stated that only basal cell cancers occur.

DIAGNOSIS

Diagnosis and therapy are the most important headings in any discussion on cancer of the skin. The general practitioner should be as well able as a dermatologist to diagnose cutaneous cancer. The specialist excels only because he is more suspicious of the various types of lesions that may be cancerous and he realizes the ease of doing a biopsy to confirm or disprove his suspicions. He does not depend on prolonged observation in order to decide what is taking place, but appreciates the need of an immediate decision. This is the crux of the whole problem of the diagnosis of cancer of the skin. I believe that teaching should more emphatically stress the urgency of early diagnosis of such lesions and that the practitioner should always be suspicious of cutaneous lesions, especially when they occur on the face, and, regardless of the age of the patient, the duration of the lesion, the type of lesion or the history, should secure a microscopic diagnosis. It seems to me futile to make elaborate and tedious descriptions of lesions or to stress topographic possibilities. I would also condemn with all the vehemence at my command the shameful practice of "watching" a lesion. The only lesion to be watched is the one proved to be noncancerous or, better still, the area from which a lesion was eradicated. I would also condemn the trial use of mild remedies such as cauterization with silver nitrate or using caustic acids. Such procedures should be outlawed.

What then is the correct diagnostic approach to suspected cutaneous cancer? The physician should be concerned with the growth itself and the welfare of the person harboring the growth; the examination of the patient is the same as employed in all diseases. A blood sample should always be taken for a Wassermann test. I believe that a serologic test should be made for every dermatologic patient, and it should be insisted on in the presence of an ulcer or tumor.

The inspection and palpation of the lesion reveals its size, shape, consistency and attachments. Close scrutiny discloses the condition of the immediate surrounding tissue. An inflammatory halo, elevation, scaling or induration usually means that the border of the lesion is beyond the visible outline. The adjacent lymphatic nodes should always be palpated. A crust should be gently removed and the character of the base noted. White scar tissue in the base is a welcome finding, while deep ulceration indicates invasion. But even the most careful examination does not reveal the true character of the growth. An excision must be made from the most active border; large enough and deep enough to give the pathologist a representative section. For my own part I see no valid objection to performing a biopsy. I am certain the prognosis is not altered one iota and the advantages far outweigh any possible objection. Neither do I believe that the small delay incurred is important.

To summarize, the clinical diagnosis of cutaneous cancer is a matter of sensible suspicion. The positive diagnosis rests on the excision of tissue for microscopic study.

out the tissue. The exact nature of these cysts was not determined by this procedure. Paraffin sections revealed a chronic granulomatous lesion containing areas of caseous necrosis scattered in a collagenous matrix. In many areas there were pseudotubercle formations with foreign body giant cells and epithelioid proliferation (fig. 2). Scattered in the caseated areas were refractile bodies which under higher magnification appeared as ova with definite refractile shells (fig. 3). Many of these were distorted by shrinkage, but occasionally one saw a suggestion of a subterminal spur. These ova appeared to be of Schistosoma. Surrounding the pseudotubercles were zones of lymphocytic and eosinophilic infiltration and early connective tissue proliferation (fig. 4). The giant cells that were seen were of the Langhans type. Immediately adjacent to these giant cells, one occasionally saw several clumps of these ova in nests of two to five cysts.

The section of brain showed pronounced glial reaction, typical perivascular cuffing and degeneration of the normal brain tissue (fig. 5).

The pathologic lesions were those of chronic granuloma, secondary to schistosomiasis. The brain adjacent to these lesions exhibited reactive cerebritis with pronounced glial reaction.

Postoperative Course.—Immediately after the operation, the patient demonstrated a monoplegia involving the left upper extremity which improved steadily until it was barely detectable at the last examination, on April 25, 1947. The papilledema subsided promptly. The patient showed a mental disturbance characterized by extreme euphoria and garrulity. This cleared gradually in about four weeks.

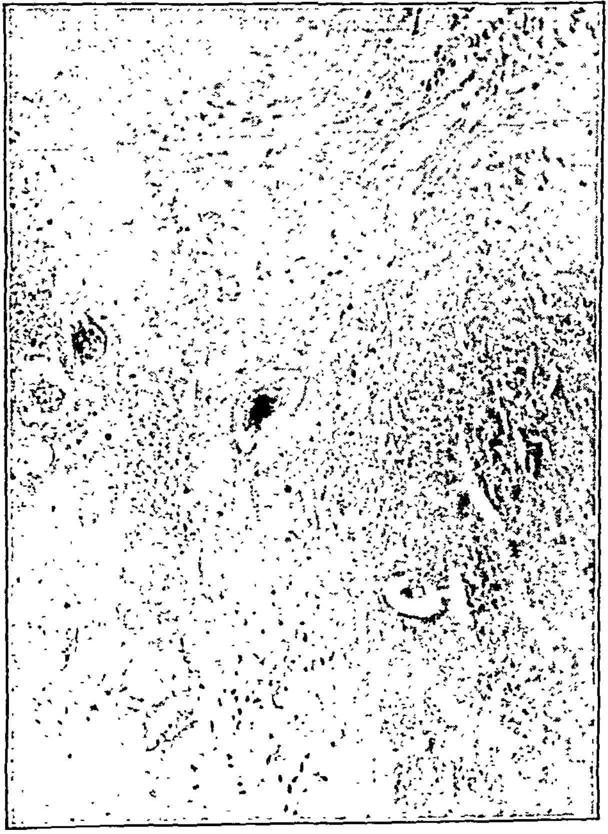

Fig. 3.—Schistosoma japonicum ova, brain. (Negative of United States Army Institute of Pathology.)

Repeated stool examinations, including sigmoidoscopy with direct smears from the rectal crypts, and repeated urinalyses failed to reveal any evidence of Schistosoma ova.

Specific postoperative therapy consisted of intravenous administration of 0.5 per cent antimony potassium tartrate every other day, beginning with 8 cc. and raising the dosage by 4 cc. each time until 28 cc. was being given. This was continued until a total of fifteen doses (0.648 Gm. of antimony) had been administered. There were no untoward reactions.

Figure 6 represents a postoperative encephalogram made on Jan. 31, 1947. The ventricular system had returned to its normal position, with some dilatation of the right lateral ventricle. The patient was discharged a week after these roentgenograms were taken.

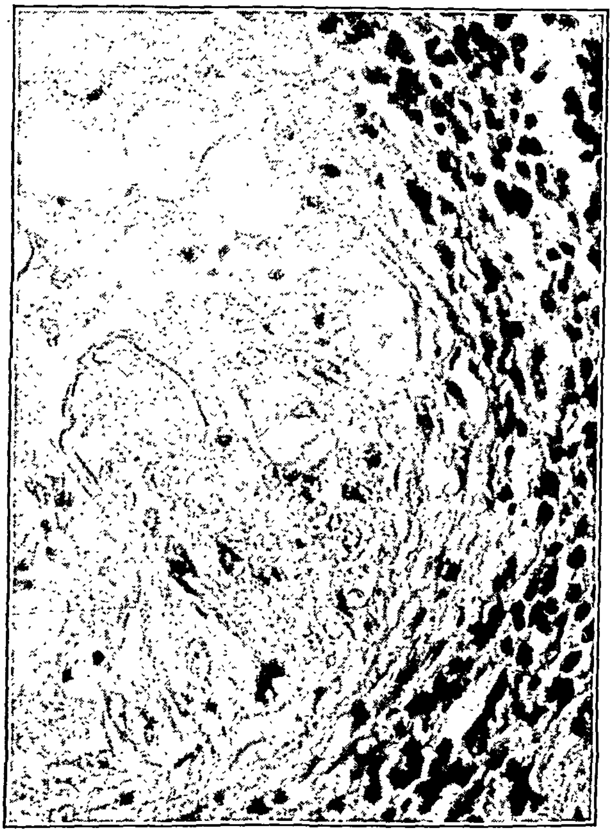

Fig. 4.—High power view of edge of pseudotubercle about the shell of an ovum, showing epithelioid cells and peripheral ring of eosinophils and lymphocytes. (Negative of United States Army Institute of Pathology.)

Neurologic survey at discharge revealed a moderate paresis of the left arm with increased deep reflexes and a positive Hoffmann response. There was no headache, and the patient appeared mentally normal and emotionally stable.

On April 25, 1947, the patient returned for follow-up examination. The weakness of the left arm was by then minimal, but the hyperreflexia and Hoffmann response persisted. Otherwise the examination remained unchanged. He had had one abortive sensory seizure the preceding day, similar to his preoperative attacks. This was the first such episode since Nov. 11, 1946. The patient otherwise felt well, although he had not returned to full time employment. He was placed on diphenylhydantoin sodium, 0.1 Gm. three times daily, at this time.

COMMENT

There are three varieties of the Schistosoma: mansoni, haematobium, and japonicum. The japonicum variety is endemic in Japan, China, Formosa, the Philippines and the Celebes, and is in all probability the infectious agent in this case. Positive microscopic diagnosis was not possible, however. Reports of neurologic complications of the haematobium variety are rare in the literature, and those of S. mansoni even more so. The latter is said to favor the spinal cord.[4]

The disease has been described as consisting of three phases, merging into one another: the first from the penetration of the cercaria to the settling of the mature worms in the venous system (usually mesenteric); the second, the period of egg laying and dissemination, and the third, the development of cirrhosis of the liver, splenomegaly, intestinal and vesical polyposis secondary to reparative processes and chronic irritation. The nervous system apparently may be involved early, when the acute systemic manifestations are in evidence. Egan[5] in 1936 reported an outbreak in which 2 persons were afflicted with severe delirium and diffuse neurologic signs. Speigel[1c] mentioned this phenomenon briefly. Spiridon[6] in 1936 and Tillman[7] in 1945 reported similar complications associated with acute outbreaks of the infection. The neurologic involvement is, in these cases, obviously a complication of the acute systemic disease and responds with the systemic disease to specific treatment. Diagnosis is not difficult, as the ova are readily demonstrable in the stools.

[4] (*a*) Müller, H. R., and Stender, A.: Bilharziose des Rückenmarkes, unter dem Bilde einer Myelitis dorsolumbalis transversa completa, Arch. f. Schiffs- u. Tropen-Hyg. 34: 527-538, 1930. (*b*) Schistosomiasis Japonica, Bull. U. S. Army M. Dept. 4: 273-276, 1945.

It is the late complications with which we are most concerned, both because these are the cases which will likely be seen in this country and because they may be extremely difficult to diagnose prior to operation or autopsy. Of the 11 cases in which operation has been performed to our knowledge[8] in only 1 (Swanson's) was the true diagnosis seriously entertained before surgery. There was a clearcut history of infection in one and a doubtful history in another. In 1 of those without a suggestive history of infection, the ova were found in the stools postoperatively. In all others the stools were negative.

As to the gross pathologic lesion, almost all of the heretofore reported cases in which operations were done have shown unilateral massive granulomas containing ova, occipitoparietal or temporoparietal in location. This, with certain histologic observations, has given rise to the opinion, no doubt well founded, that the maternal organism was in one of the great cerebral sinuses or veins, and her egg deposits were therefore well localized. Hence the mass lesion.

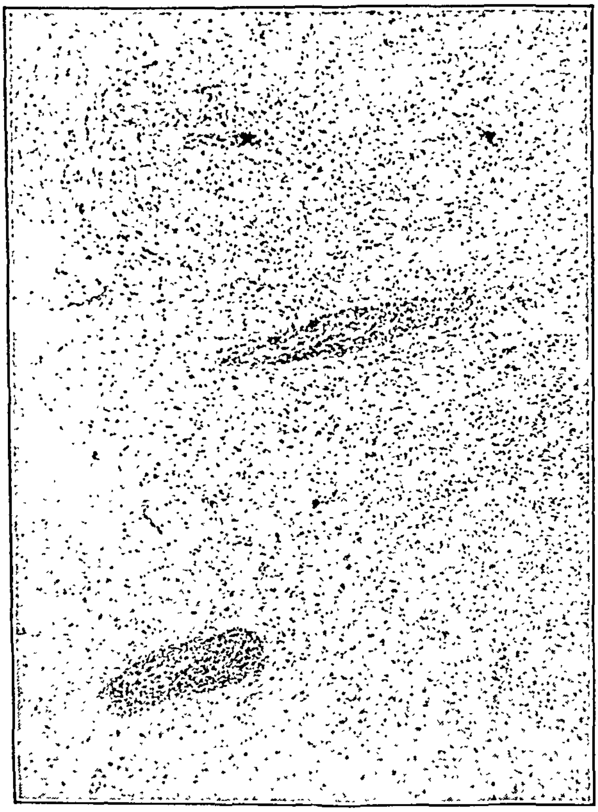

Fig. 5.—Reaction in adjacent brain tissue, showing prominent vascular cuffing; schistosomiasis, brain. (Negative of United States Army Institute of Pathology.)

On the other hand, favoring a more diffuse embolic process are the autopsy observations of Vitug, Cruz and Bautista[9] of bilateral diffuse lesions and the autopsy observations of Tsunoda and Shimamura[10] of unilateral diffuse left hemispheral lesions. Ours is one of the first cases, to our knowledge, in which operation was done which fell into this group of diffuse lesions. It is probable that both mechanisms of deposition are operative.

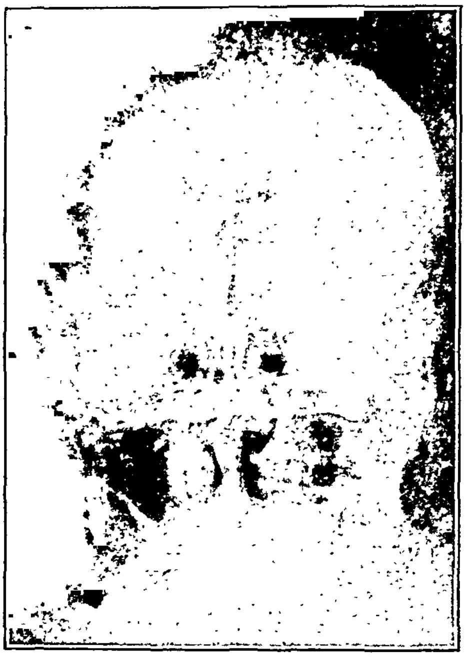

Fig. 6.—Anteroposterior view of the skull taken postoperatively after the introduction of air into the lumbar subarachnoid space.

With regard to the clinical manifestations, they are those of an intensely irritative focal or diffuse lesion producing headache, epileptiform seizures, focal neurologic signs and, in about one half the cases reported, papilledema. The difficulties in differential diagnosis between this condition and brain tumor can easily be appreciated. Blood eosinophilia and ova in the stools are uncommon at this stage of the disease and, at best, offer only presumptive evidence.

In view of the rarity of the lesion and the frequent development of large intracerebral masses, it would seem that most patients must still be subjected to operation for diagnostic as well as therapeutic reasons. In our case, however, it seems probable that surgical treatment would not have been necessary had positive diagnosis been possible by clinical and laboratory methods. All patients should be treated specifically with either stibophen or antimony potassium tartrate. The latter is felt by most authorities to be the most effective drug, although it is considerably more toxic.[11] Under this therapy the prognosis for life would appear to be excellent, although neurologic disabilities, particularly convulsive seizures, are frequent residuals.

SUMMARY AND CONCLUSIONS

A case of diffuse granulomas and cerebritis due to schistosomiasis is reported. Surgical treatment with subsequent administration of one of the antimony compounds would seem to give satisfactory results in these cases.

ENDOMETRIOSIS IN A YOUNG GIRL

ALFRED HULL CLARK, M.D.
Buffalo

Dr. John Fallon of Worcester, Mass., in the summer of 1946, reported 9 cases of endometriosis in girls under 20. Up to the time of his report endometriosis was not looked for in persons of teen age. Fallon drew attention to endometriosis as the cause of dysmenorrhea even in young girls.

The case herein reported is, as far as I know, that of the youngest girl yet reported in whom symptoms referable to endometriosis appeared.

B. S. was born Dec. 2, 1932. In August of her eleventh year, 1944, she had a slight, though definite, pain in the lower left quadrant of the abdomen, which lasted for three or four days. The pain recurred every month until after her twelfth birthday, when she first menstruated. At this time, April 1945, her first period was accompanied with the same pain noticed each of the previous months, but slightly greater. Thereafter the pain with each period became severer. It started every month the day before the period and lasted four or five days. There was often vomiting, usually after oral medication. There was a gradual change in personality. The girl became moody and somewhat unsocial. Treatment with sedatives, estrogens and other medicaments were useless. It was not until treatment with opiates was resorted to that the pain was controlled. Finally, one of several physicians who had seen the patient sent her in for resection of the presacral plexus. Examination, because of virginity and a fat abdomen, was not satisfactory, and a diagnosis of endometriosis was not made until the abdomen was opened, although dysmenorrhea, increasing each month, should have served as a diagnostic point.

At operation the omentum was seen to be wrapped around a mass attached to the left cornu of a bicornate uterus. When this mass, with the attached omentum, was removed, it measured 6.5 by 3 by 3 cm. There was a smaller separate mass, 3 by 1.5 by 1 cm., on the anterior surface of the left broad ligament. Dr. Anthony Postoloff, pathologist at the Millard Fillmore Hospital, from the examination of both masses, gave the diagnosis of endometriosis. Neither ovary was involved. The larger mass was made up of several small cysts, the largest cyst was 1 cm. in diameter and all the cysts were filled with a chocolate-colored viscous substance.

There was no pain during any of the three menstrual periods since the operation, and the girl is again normal.

The periodic pain occurring for eight months before the menarche is suggestive of cyclic changes in the endometrium before actual bleeding occurs. It may be that swelling of the endometrial tissue in the closed cysts caused the pain.

Council on Foods and Nutrition

The following products have been accepted as conforming to the Rules of the Council.

JAMES R. WILSON, M.D., *Secretary.*

Libby, McNeil and Libby, Chicago, Ill.

LIBBY'S STRAINED AND HOMOGENIZED APRICOT-FARINA consists of apricots, water, dextrose, *farina* and salt.

Analysis (submitted by manufacturer).—Total solids 20.59%, moisture 79.41%, crude protein 0.87%, fat (ether extract) 0.06%, ash 0.53%, crude fiber 0.35%, carbohydrates other than crude fiber (by difference) 18.78%.

Calories.—0.79 per gram; 22.44 per ounce.

Vitamins and Minerals.—Content per hundred grams: vitamin A, 2,634 U. S. P. units; thiamine, 0.013 mg.; ascorbic acid, 2.10 mg.; riboflavin, 0.022 mg.; niacin, 0.30 mg.; salt (NaCl), 350.00 mg.; calcium, 12.50 mg.; phosphorus, 18.10 mg., and iron, 1.03 mg.

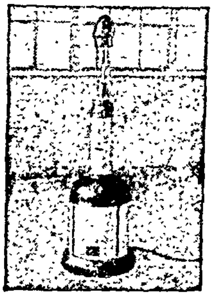
Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, *Secretary.*

HANOVIA "LIGHTHOUSE" PORTABLE LARGE GROUP IRRADIATION ULTRAVIOLET LAMPS ACCEPTABLE

Manufacturer: Hanovia Chemical & Mfg. Company, Chestnut Street and N.J.R.R. Avenue, Newark 5, N. J.

These lamps, Models 2143 and 2145, are sources of ultraviolet radiation. They are the same in most particulars except the power consumption and intensity of radiation output; Model 2143 has a 550 watt burner and Model 2145 has a 700 watt burner. The generating lamp is of the high-pressure low-voltage mercury arc type and is enclosed in a quartz tube. The assembled apparatus is designed to be set in the center of a room to permit the simultaneous irradiation of a group of 12 or more patients in the standing position, the lamp being about 1.2 meters (4 feet) above the level of the floor.



Hanovia "Lighthouse" Models 2143 and 2145.

One lamp (Model 2143) was investigated in a clinic acceptable to the Council on Physical Medicine. This lamp produced a minimal erythema dose on untanned skin in five minutes at a distance of 2.1 meters (7 feet) as claimed by the manufacturer. The appearance and durability of the apparatus were good.

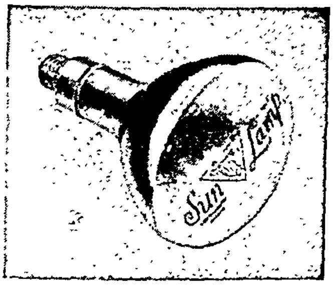
The Council on Physical Medicine voted to include the Hanovia "Lighthouse" Portable Large Group Irradiation Ultraviolet Lamps, Models 2143 and 2145, in its list of accepted devices.

ARTRON SUN LAMP, TYPE A, ACCEPTABLE

Manufacturer: Hytron Radio & Electronics Corp., 76 Lafayette Street, Salem, Mass.

Distributor: Affiliated Retailers, Inc., Empire State Building, New York 1.

The Artron Sun Lamp, Type A, is of the bulb type, containing a filament within a small quartz capsule that houses the mercury arc. The power required for operation is 275 watts on a 110 to 125 volt A. C. circuit. Except for the fact that it bears the etched name "Artron," this lamp is identical with the Hytron Sun Lamp, Type A, manufactured by the Hytron Radio & Electronics Corp. It is similar in construction to the General Electric and Westinghouse lamps of Type RS. The Artron Sun Lamp is made especially for the Affiliated Retailers, Inc., Empire State Building, New York 1.



Artron sun lamp, Type A

An investigator for the Council verified the erythematogenic effectiveness of the lamp. He made three exposures, side by side, of the untanned inner upper arm, at a distance of 24 inches (61 cm.) from the front edge of the lamp, for periods of five, ten and fifteen minutes, respectively. After three hours, the fifteen and ten minute exposures were very red and the five minute exposure showed a faint reddening. One day later only the ten and fifteen minute exposures were still red. They were still red three days after the irradiation, but they were not tender as they would be if there had been blistering. He concluded that the manufacturer's recommendation of exposure not longer than five minutes was correct.

The Council on Physical Medicine voted to include the Artron Sun Lamp, Type A, in its list of accepted devices.

HANOVIA ONE BURNER GROUP IRRADIATION ALPINE CEILING LAMP ACCEPTABLE

Manufacturer: Hanovia Chemical & Mfg. Company, Chestnut Street and N.J.R.R. Avenue, Newark 5, N. J.

This lamp, Model 2137, is an ultraviolet radiation generator and is designed to be fastened to the ceiling. Regulation of the intensity of the ultraviolet radiation is controlled from a floor-type cabinet. It has five steps of intensity control. The burner is a high-pressure low-voltage mercury arc lamp in a quartz tube and requires 700 watts of electrical power. The transparent fused quartz tube is provided at each end with electrodes of the incandescent tungsten filament type.

Hanovia Model 2137.

The central fixture consists of a hood which may be suspended from the ceiling in the middle of the room at a distance of about 2.1 meters (7 feet) above the cots. The firm claims that at this distance the maximum intensity of radiation, 3,130 angstroms and shorter, on the cots with the control set for minimum intensity is 200 microwatts per square centimeter. This intensity will produce an erythema on the untanned skin after five minutes' exposure.

The lamp was investigated in a clinic acceptable to the Council and the claims of the manufacturer were confirmed.

The Council on Physical Medicine voted to include the Hanovia One Burner Group Irradiation Alpine Ceiling Lamp, Model 2137, in its list of accepted devices.

CALIFORNIA DRI-AIRE LAMP NOT ACCEPTABLE

Manufacturer: California Therapy Equipment, Inc., 5982 West Pico Boulevard, Los Angeles 35.

The California Dri-Aire Lamp is essentially an infrared lamp. It stands on the floor, is adjustable in height, can be set at various angles and has a shepherd's crook neck so that its rays can be directed on a bed or on a seated patient.

The firm states that the lamp operates on either direct or alternating current, requires 110 volts and draws 500 watts of electrical energy. According to the manufacturer, "Its intensity can be increased or decreased by moving the lamp closer or away from the person using it. The coating on the element cuts down rays such as ultraviolet and intensifies the infrared," and the lamp has approval of Underwriters' Laboratories.

The illustrations in the advertisements show an object that looks like a switch attached to the power supply wire. However, the lamp sent to the Council office for examination had no switch and had to be turned off by pulling out the plug.

The firm submitted copies of a full page advertisement. Much emphasis is laid on the ability of this lamp to "provide a zone of warm, dry air similar to the soothing, quality air of the desert." There is, of course, nothing in the lamp to exercise a special dehumidifying effect; by heating the air in its vicinity it reduces the relative but not the absolute humidity. It cannot, obviously, make dry desert air out of the humid air of a hot day in Chicago, for example. Thus the firm's claim that the apparatus "brings soothing, healing, dry, warm desert air wherever and whenever you want it" is misleading. The classification which includes neuritis and sacroiliac pain among "circulatory ailments" is inaccurate.

On the basis of its construction, which shows no advantages over similar products of other manufacturers, and of the advertising, which contains inadmissible claims, the Council on Physical Medicine voted not to include the California Dri-Aire Lamp in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement. Austin Smith, M.D., *Secretary.*

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry convened at 9:30 a. m. Nov. 14, 1947, for a two day meeting at the headquarters of the American Medical Association. In attendance were the following members: David P. Barr, Paul R. Cannon, S. W. Clausen, Morris Fishbein, E. M. K. Geiling, Chester Scott Keefer, C. Guy Lane, James P. Leake, Robert F. Loeb, Perrin H. Long, G. W. McCoy, Stuart Mudd, E. M. Nelson, Austin Smith, Torald Sollmann, Isaac Starr and W. Barry Wood Jr. Also in attendance, in addition to members of the headquarters staff and members of the Therapeutic Trials Committee, were Dr. Robert Stormont, medical director of the Food and Drug Administration; Dr. Milton Veldee, chief, Biologics Division of the National Institute of Health; Dr. Donald A. Wallace, secretary of the Council on Dental Therapeutics; and Dr. E. Fullerton Cook, chairman of the Pharmacopeial Revision Committee.

The first order of business was the election of officers. Torald Sollmann was reelected chairman and James P. Leake vice chairman. The Council then proceeded to the consideration of topics on the agenda.

The Council considered problems associated with the use of multiple dose containers, emphasizing particularly the transmission of the agent responsible for homologous serum jaundice and the inadequacy of preservatives to prevent the transmission of some infectious agents, particularly when the menstruum may be a good medium for bacterial, fungous or virus growth. After extended discussion a committee was appointed to bring definite recommendations to the Council.

The present status of thyroxin was reviewed, and it was concluded that the usefulness of this drug and the dangers associated with its use do not justify its continuance in New and Nonofficial Remedies. It was therefore voted to omit it from the next edition (1949). Manufacturers with accepted brands will be informed of this action.

The status of "scillaren" was discussed, and while it was agreed that this squill preparation has only limited use and value, such as would be the case in the presence of apparent sensitivity to digitalis, it was decided that this agent could be continued in New and Nonofficial Remedies unless there was evidence of its misuse by the members of the medical profession. It is believed that the scope of New and Nonofficial Remedies include drugs which, although their actual use is limited, are nevertheless effective and possess usefulness.

Because untoward reactions such as fever, rash, acute leukemia, leukopenia and other manifestations of toxicity developed in approximately 18 per cent of patients who receive sulfathiazole (which compares with about 16 per cent for sulfapyridine, 12 per cent for sulfanilamide, 6 per cent for sulfadiazine and 7 per cent for sulfamerazine), the Council questioned the need for continuing the acceptance of this drug inasmuch as other sulfonamide compounds, penicillin and streptomycin are now available. Accordingly, a motion was adopted to omit sulfathiazole from the 1949 edition of New and Nonofficial Remedies and to notify all manufacturers and distributors of accepted brands. This conforms with the Council's policy of withdrawing acceptance of a toxic drug when a less toxic but equally effective agent becomes similarly available. Because of its side effects sulfapyridine has been omitted from New and Nonofficial Remedies.

The use of a sulfonamide ointment for prophylactic (venereal) purposes was discussed and a committee appointed to report back to the Council. This consideration followed the Council's recent decision to discontinue recognition of the local use of sulfonamide drugs (The Journal, Sept. 20, 1947, p. 157).

A related topic of discussion was the use of mixtures of sulfonamide compounds, which have received some attention because of claims that such mixtures permit effective treatment with lower doses and fewer side reactions. Formal action on this problem was not taken. The Council reviewed the criteria necessary to justify acceptance of mixtures of drugs and voted to appoint a committee to study this problem and present a report on the application of the rules to mixtures.

The sale of "over the counter" items for reducing has produced a problem of great health and economic significance. Much money is being spent for useless preparations, and many persons are attempting to treat themselves with useless or, as the case may be, dangerous remedies. The Council stands for rational, honest therapeutics and not for deceit or quackery. Therefore it was voted to prepare for publication several articles on this subject.

Remedies for motion sickness appear to be receiving increasing attention in general advertising, which creates a health problem. Because some of the ingredients sometimes used are potentially dangerous when given in effective doses and fraudulent if provided in smaller doses, the Council authorized preparation of a review of this subject for publication.

The Council is continually reviewing the rules by which it functions and considers, especially those regulations that seem to be less well understood. The recognition of names is one of these, and a series of proposals was made at this meeting to permit the best possible understanding of the objectives of the Council and of ways of meeting the objectives. Any changes in the editing of the rules that may be adopted by the Council will be incorporated when the rules are republished, as they are each year in New and Nonofficial Remedies and in a booklet available on request from the office of the secretary of the Council.

The Council further reviewed the status of influenza vaccines and the effect of new strains of influenza virus. No action was taken other than to insure that in New and Nonofficial Remedies the statements for influenza vaccines be specific in claiming that such preparations are effective only against the strains included in the particular vaccine described. It was the consensus that much remains to be learned concerning the usefulness of such products.

The Council considered how best to keep abreast with changes in immunization dosages and technics and during the discussion adopted a motion recommending that the National Institute of Health be asked to publish periodically its minimal standards for biologics.

The status of mixed vaccines that contain materials for immunization against typhoid and paratyphoid A and B was reviewed, and the Council voted to delete this mixture from New and Nonofficial Remedies and to accept from Jan. 1, 1948 only the typhoid vaccine for civilian typhoid prophylaxis.

The Council recently voted to recognize "methadon" as a generic name for 6-dimethylamino-4-,4-diphenyl-3-heptanone (The Journal, Aug. 23, 1947, p. 1483). A question was raised concerning the possibility of this being confused with metopon, an opium derivative. After due deliberation it was the consensus that the possibility of confusion is not great and that no further action need be taken at this time.

Because of the inherent dangers of thiouracil and the efficacy of propylthiouracil, which provides all the benefits that could be expected from thiouracil with a mere fraction of the unfavorable actions, the Council voted to omit thiouracil from New and Nonofficial Remedies.

The Council was informed that the Board of Trustees of the American Medical Association found it impossible to continue providing funds for the distribution of complimentary copies of New and Nonofficial Remedies to students in approved medical schools. Printing costs have forced discontinuance of a practice that has been in effect for over twenty years.

A report of the activities of the Therapeutic Trials Committee revealed this standing committee to be established already with the knowledge that it is fulfiling a function that cannot be fulfilled by any other existing agency, particularly in two large projects now before the committee, namely, the effect of steroids on cancer and the treatment of anterior poliomyelitis. The work of the committee was commended highly and the report was approved.

The report of the Therapeutic Research Committee, which issues grants for research, was placed before the Council and was approved as made.

The status of protein hydrolysates and concentrates, amino acid mixtures and amino acids was reviewed.

Comment was requested on the advisability of continuing to publish the tests and standards section of New and Nonofficial Remedies in The Journal, and it was decided that this practice should be continued, especially in view of the wide circulation of The Journal to foreign countries.

Consideration was given to manufacturers whose activities have been made the subject of court investigation and record and who have submitted articles to the Council for inclusion in New and Nonofficial Remedies.

The rules of the Council provide that articles which have been official for twenty or more years may be deleted from New and Nonofficial Remedies. To take care of the problem associated with protected names that have been recognized by the Council, it was agreed that such names might be transferred to an addendum to New and Nonofficial Remedies, in which could be given sufficient data on such preparations.

Consideration was given to the possibility of closer cooperation with the Pharmacopeial Revision Committee through the issuance of a joint publication on drugs. A committee was appointed and instructed to study the proposal and report back to the Council.

The Council also gave consideration to the advisability of continuing its insistence on the name of the salt being included in the drug titles that are accepted for inclusion in New and Nonofficial Remedies. One manufacturer raised the possibility of legal difficulties because some pharmacopeial names do not include the salt. However, after considering all the factors involved the Council reaffirmed its previous decision that the name of the salt, when such exists, must appear in the title when the drugs are accepted for inclusion in New and Nonofficial Remedies.

The Council also gave consideration to the mention of experimental uses of drugs accepted for inclusion in New and Nonofficial Remedies in promotional material and, decided that appropriate explanatory statements could be carried in the rules to cover this point. At the same time the members reviewed the question of inclusion of accepted and nonaccepted articles in the same advertising material, and again it was decided that appropriate explanatory comments could be framed to handle this problem.

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement which will appear also in the 1948 edition of New and Nonofficial Remedies. It is published in The Journal *because of the intensity of current interest in amino acids and modified protein preparations.*

Austin Smith, M.D., *Secretary.*

PROTEIN AND AMINO ACID PREPARATIONS

Protein and amino acid preparations may be conveniently divided into two general classes: (1) mixtures of those amino acids considered essential to human nutrition that are used to combat protein deficiency imposed by severe illness or starvation; (2) individual amino acids that may be used for specific therapeutic purposes.

Preparations in the first class include (*a*) hydrolysates of protein or sources of protein prepared by various methods of artificial digestion designed to provide adequate amounts of the essential amino acids, and (*b*) mixtures of synthetic amino acids. Preparations in the second class include any of the individual amino acids that may be specifically indicated for the treatment of disease. Aminoacetic acid (glycine), formerly used in the treatment of myasthenia gravis, and histidine, which has been tried for the treatment of peptic ulcer, are examples of this type, though neither are currently recognized to be of specific value in these conditions. Neither methionine nor lysine, although promising for the treatment of disease of the liver, has been definitely established to be of specific therapeutic value for that condition.

While mixtures of the essential amino acids are presently recognized to exert a favorable antacid and nutritive effect in peptic ulcer, their primary purpose is to supply dietary nitrogen in readily assimilated form when there is serious interference with the intake, digestion or absorption of dietary protein. There is no evidence that the addition of amino acids to foods will accomplish anything that cannot be accomplished by proper use of proteins as they occur naturally in the diet when there is no such interference.

The amino acids that are now regarded as indispensible for protein synthesis in adult man comprise those which the body is itself unable to synthesize and are generally listed as follows: phenylalanine, tryptophane, methionine, lysine, leucine, isoleucine, threonine, valine, histidine and arginine. These ten amino acids or their precursors are usually provided in mixtures intended for protein replacement in human beings but there is some doubt at present about the indispensability of histidine and arginine in adult man.

As yet there is insufficient information on which to set up exact dosage estimates for the amino acids that are prescribed to meet protein needs of the body. The daily requirements for the individual amino acids are under investigation, and there are indications that these range from 0.3 to 5 Gm. each per day. Until more is known of human requirements, amino acid preparations must be given in sufficient quantities to provide every essential constituent in substantial amounts. This may be based on the commonly recommended optimum daily intake of total dietary protein: 1 Gm. per kilogram of body weight, or about 70 Gm. daily for the average adult man. This figure is based on the fact that on a mixed diet the average protein intake necessary to maintain nitrogen balance has been found to be about 45 Gm. There are wide variations in individual requirements and also wide variations in the biologic value of proteins from different sources, but it is estimated that the amino acid requirements will ordinarily be met on a diet containing 70 Gm. of protein.

Amino acid mixtures have appeared on the market in various forms: protein hydrolysates or hydrolytic products of good sources of protein in solution or powdered form for oral administration or intravenous injection; mixtures of amino acids in tablet form; synthetic amino acids in tablet form; synthetic amino acids combined with vitamins in tablets and elixirs; protein meals for use in tablets or food fortification. Most tablets or elixirs supply insignificant amounts for rational use in human nutrition.

Thus far, the Council considers as acceptable for nutritional purposes only those mixtures that provide adequate amounts of each of the essential amino acids. For the present, and until more evidence becomes available, the Council restricts acceptance of such amino acid mixtures for either oral or intravenous administration to hydrolysates of suitable pure proteins (such as casein) or good sources of protein (such as blood) in which more than 50 per cent of the total nitrogen present is in the form of alpha amino nitrogen. This minimum degree of hydrolysis is considered essential to justify the designation of such products as hydrolysates and to reduce the nonantigenic properties of the mixtures used for intravenous injection and those used orally for infants and children who may be allergic to protein of the diet. The Council requires that evidence of nonantigenicity for each product should be submitted. The Council has permitted the addition of carbohydrate to such hydrolysates in proportions suitable for injection. The Council has not, as yet, accepted preparations containing added vitamins or other substances considered essential for adequate nutrition pending adequate justification for such preparations.

Hydrolysates of pure proteins such as casein, lactalbumin and fibrin are properly described as protein hydrolysates and are defined under this general heading in the monograph which follows. They may be designated as "Casein (Lactalbumin, Fibrin) Hydrolysate." Hydrolysates of good sources of protein such as blood, liver and yeast are distinguished from pure protein hydrolysates and will be individually described under separate generic designations appropriate to indicate their respective derivation, e. g., Blood (Liver, Yeast) Hydrolysate. Restoration or addition of amino acids to hydrolysates should be limited to those considered essential for human nutrition and should be sufficient to furnish the equivalent of the biologically active form in an amount proportionate to the original source or to meet actual requirements if the quantity needed is known. Products to which one or more amino acids have been restored or added or in which one or more of them have been at least partially removed should be designated as "Modified Casein (Liver, etc.) Hydrolysate." When carbohydrate such as dextrose has been added, the designation of such preparations should be expanded to indicate the carbohydrate component, e. g., "Modified) Casein Hydrolysate with Dextrose ( ) %." When such products are supplied in the form of solution for intravenous injection, the designation should be prefixed by the word "Solution" and include the per cent of hydrolysate provided, e. g., "Solution Casein Hydrolysate 5 per cent (with Dextrose 5 per cent)." Such designations do not preclude, but should be adequately displayed with, acceptable trademark names. The Council requires that all hydrolysates be labeled with the appropriate generic designation (to include dextrose or other suitable carbohydrate when this is added); the identity of the protein or source of protein from which they are derived when this is not declared in the descriptive designation; the method of hydrolysis (acid, enzymatic or other); the nature of modification in amino acid content after hydrolysis (if any); the percentage of each amino acid or its equivalent that is present, and the percentage of alpha amino nitrogen that is represented in relation to the total nitrogen content of the mixture. Council consideration of hydrolysates for acceptance is further predicated on adequate rat growth studies to demonstrate nutritive value and in the case of intravenous products also on adequate clinical evidence to demonstrate freedom from antigenic, pyrogenic and toxic properties. Claims for special therapeutic purposes of hydrolysates other than for general protein deficiencies must be supported by specific scientific evidence.

Pure synthetic mixtures of amino acids to be used for nutritional states or preparations of the individual pure amino acids for specific therapeutic purposes will be given consideration as evidence for their usefulness is established. Preparations of intact proteins used orally as food supplements are considered to be outside the purview of the Council unless specific therapeutic value is established for such products.

PROTEIN HYDROLYSATES

These are broadly defined as artificial digests of protein derived by acid, enzymatic or other hydrolysis of casein, lactalbumin, fibrin or other suitable proteins that supply the approximate nutritive equivalent of the source protein in the form of its constituent amino acids. They are required to have more than half of the total nitrogen present in the form of alpha amino nitrogen. Such preparations comprise (*a*) unmodified products in which there is neither partial removal nor restoration of any of the original amino acid precursors and for which the designation "protein (or casein etc.) hydrolysate" is restricted and (*b*) modified products to which one or more amino acids have been added or one or more of them have been at least partially removed after hydrolysis and for which the designation "modified protein (or casein etc.) hydrolysate" is required. Other labeling requirements and the permissible modifications in amino acid composition or the addition of carbohydrate are set forth in the foregoing general statement on Proteins and Amino Acid Preparations.

Actions and Uses.—Parenteral preparations are useful for the maintenance of positive nitrogen balance in conditions where there is interference with ingestion, digestion or absorption of food. These conditions are most frequently encountered in severe illness and after surgical operations involving the alimentary tract. In the acute catabolic phase of nitrogen loss in healthy persons who become suddenly ill, it may be extraordinarily difficult to achieve nitrogen balance with the amount of hydrolysate which can be administered. The acute nitrogen loss of brief severe illness has not been shown to be pernicious, and it is debatable whether hydrolysates should be employed under these circumstances. Protein hydrolysates should not be employed as a substitute for food proteins if the latter can be adequately utilized. Intravenous injection is contraindicated in severe hepatic insufficiency and in acidosis until the latter condition is corrected. Injection may produce untoward effects such as nausea, vomiting, hyperpyrexia, vasodilatation, abdominal pain, convulsions, edema at the site of injection, phlebitis and thrombosis. Care must be exercised in looking for reactions that indicate danger. Many unfavorable reactions have been traced to inadequate care in the cleanliness of equipment and also to too rapid administration of the preparation. Solutions that are cloudy, that contain sediment or that have been opened for a previous injection should not be used. Unopened solutions should be stored in a cool place.

Claims for oral use of protein hydrolysates that are shown to be adequate nutritionally should, for the present, be limited as follows: (1) in the diet of infants allergic to milk when the allergy cannot be met by other foods; (2) in the treatment of peptic ulcer and in ulcerative colitis if acceptable evidence is submitted pertaining to the product concerned, and (3) in supplementing the diet in conditions in which a specially high protein intake is indicated, when it is not feasible to accomplish this by use of ordinary foods.

Claims for supplementing the protein in other conditions are not permissible, because there is no evidence of need for such supplementation and if it should exist it could be met by the use of ordinary foods

Dosage.—See the foregoing general statement on Protein and Amino Acid Preparations. Until more is known of the individual requirements for the amino acids, the dosage to be given should be designed to supply substantial amounts of all those considered essential to meet the protein needs of the body

SATURDAY, MARCH 6, 1948

A NATIONAL HEALTH ASSEMBLY

Mr. Oscar R. Ewing, federal security administrator, has announced the calling of a National Health Assembly in Washington, D. C., May 1-4. President Truman wrote a letter to Mr. Ewing reminding him that he (Mr. Truman) had repeatedly requested Congress to enact legislation designed to expand basic health services. The President said, "The attainment of such a goal requires the cooperation of state and local governments, voluntary organizations, the medical and health professions, as well as our citizens working together." He requested Mr. Ewing to make a comprehensive study of the possibilities of raising health levels and to report on the feasible goals which might be realized by the American people in the next decade. As a first step, Mr. Ewing announced on February 15 the appointment of "twenty-four national leaders" who had been invited to serve on the executive committee of the assembly. The assembly is to be held in the form of panel discussions, each of which will explore a specific phase of the health problem. It was anticipated that some seven hundred to eight hundred persons would attend the sessions. When Mr. Ewing made his announcement to the press, an interviewer asked him whether or not there were any political implications; the newspapers reported that he said any activity during convention year might be considered political.

Thus far the National Health Assembly bears all the stigmas—political and propagandistic—that accompanied the National Health Assembly of 1938. Under the leadership of Miss Josephine Roche that congress was overwhelmed with representatives of agencies promoting nationalized medicine in the form of compulsory sickness insurance as the one answer to the medical problem. Mr. Truman has twice affirmed his support of compulsory sickness insurance along the lines covered by the Wagner, Murray, Dingell legislation. The present executive committee includes twenty-four names already announced, of which only one is a physician; nineteen of those named have previously been associated with propaganda in behalf of compulsory sickness insurance. Mr. Ewing has added the names of three other physicians, but thus far a public announcement has not appeared. The conference of 1938 was organized with a preponderance of representatives of nonmedical groups. The nonmedical speakers were given the major portion of time on the radio, and the publicity, which was in charge of Mr. and Mrs. Ernest Lindley, greatly emphasized the propaganda in behalf of compulsory sickness insurance. The speakers, representative of governmental agencies, were given almost unlimited time and the program, which was announced by Isidor Falk in an address of more than an hour and a half, was the government's program. Actually the government's program had been fully prepared and was presented for the first time at the conference, and no attempts were made to elicit, nor was opportunity given for consideration of any other program or, indeed, for a detailed discussion of any part of the government's program. In other words, the National Health conference of 1938 was designed as propaganda and participation by the medical profession merely gave it an authenticity that it did not merit.

Mr. Ewing assures the American people in his announcement that "meeting together, spokesmen for the medical and health professions, for our great national voluntary health organizations, and for the citizens generally will have an opportunity to examine every facet of the problem." He calls for teamwork on the problems that concern all of us and he believes that the assembly will establish "a clearer picture of just how much agreement there is in certain supposedly controversial health fields." The medical profession, having participated in the conference of 1938, which was in no sense of the word a conference, cannot be condemned if it views with reluctance a call for a similar assembly, particularly in an election year and particularly just before the major political parties will be drafting the platforms on which they propose to seek public support. No doubt an assembly of qualified leaders in the field of health and medicine and research could assemble around a table or even in a small hall and by free interchange of information, experience and opinion develop a program for the nation's health which would lead to intensified activity and progress during the next ten years. Whether or not seven hundred persons can get together in a dozen or more panels and work out similar advancement is, of course, questionable. Granting that panels of thirty or forty persons can discuss the problems that will be put before them each day, the medical profession will still be concerned as to the ultimate fate of recommendations that may come from these panels. If they are to be submitted to the executive committee already set forth and if that committee is to have the final decision as to the recommendations that are to be announced to the public, the objectives of the medical profession are defeated before the assembly has been held.

In most such assemblies the opening speeches are given vast circulation throughout the nation over the radio and in the press. If the opening addresses are made by President Truman and Mr. Ewing, the medical profession already knows that they will be another endorsement of nationalized medical care and compulsory sickness insurance. What arrangements will be made for addresses by those opposed to such a program, and what opportunity will they have for reaching the public that would be reached by the other addresses? Is the new National Health Assembly to be simply another sounding board for a leftist medical program? These are questions that should be answered for the medical profession now! The implications involved in such an assembly are so serious for the medical profession that it should be called into early conference on the development of the program, the publicity and the ultimate use of the material developed by the conference if full participation by the medical profession is requested. The Board of Trustees of the American Medical Association at its recent meeting in Chicago reached this conclusion, and the authorities for the National Health Assembly have been informed of their opinion.

The Ten Point National Health Program of the American Medical Association is a sound platform for the advancement of the nation's health. It is being steadily implemented by activities of the Association and of voluntary and governmental agencies. If its objectives can be realized by intensified actions of medical, voluntary health and governmental health agencies, there will be little need for a nationalized medical care program. The progress that has been made in medicine and in medical care in the United States is the envy of all the rest of the world. It is an asset which the medical profession of this country cannot hold lightly and which it should not hazard in any ventures in which complete confidence has not been established.

THE PUBLIC WANTS A DOCTOR WHEN THEY WANT HIM:

He must work all day and half the night, and never say he's tired;
For the public look upon him simply as a servant hired.
And should he take a holiday, he'll find when he comes back,
Some patients have resented it by giving him "the sack."

From "The Song of the General Practitioner"
by J. Johnston, M.D., in the *Lancet.*

From many sections of the United States complaints have come lately that persons who have called physicians late at night have been unable to secure attendance from either those whom they considered their family physicians or from specialists or, indeed, from any physician. In one western community a fire chief gave to the press information to the effect that he had called twenty-four doctors and had been unable to secure attendance by any of them. A subsequent investigation indicated that he had actually talked only to three physicians and two osteopaths who had stated that the case was not within their province—(strange indeed!). Investigation also disclosed that instead of the 24 calls alleged to have been placed, only three physicians, all seriously ill with influenza, were contacted. Of the three, two informed the operator that if another doctor could not be obtained, they would go. Neither was called again.

Notwithstanding the explanation of these isolated instances, many physicians do dodge the making of calls on patients in the late hours of the night or early morning; the crowding of physicians' offices and hospitals makes difficult in large cities even the securing of a prompt appointment in the office. Some radio comedians are now using the public interest in the question as the basis for jibes at the medical profession; Groucho Marx recently said to one of his contestants, "Make an appointment with the doctor and probably you'll see him in two or three days."

Many persons and some physicians seem to believe that a doctor must respond to any call that comes to him. The law does not cover this situation as far as is known, but court decisions have ruled that a physician is not compelled to respond to an initial call. The Principles of Ethics are explicit:

> "A physician is free to choose whom he will serve. He should, however, always respond to any request for his assistance in an emergency or whenever temperate public opinion expects the service."

Interpretation of this statement should not be difficult. In one city recently a child was struck by an automobile and sustained a fracture. The accident occurred on a corner next to a great building in which were housed many physicians. Some one from the street who had seen the accident attempted to secure the services of a half dozen physicians who were at the time in their offices, yet all refused to respond to the call, offering as excuses the specialties which they practiced or the fact that they were at the moment engaged with a patient. Public opinion condemned them unequivocally; their failure to respond greatly injured the good will of the public for the medical profession in the community as a whole.

When the pressure on the medical profession becomes severe, as it is now in this postwar period, demands are likely to press too heavily on the available service. Organization of the medical profession to meet the emergency needs was a conspicuous part of the solution of wartime problems. Some communities have, however, established permanent organizations for attending to such demands. County medical societies in some areas maintain a physicians' telephone exchange which takes the responsibility for locating physicians if response is not made to the ringing of the telephone in the home or in the office. For meeting emergencies the exchange maintains a list of physicians who are willing to make calls at night. Many young physicians gladly list their names with such exchanges. The medical societies of the District of Columbia, of Milwaukee and of Oakland, Calif., have established physicians' service bureaus and have registered the names of physicians who are willing to respond to calls from persons unknown to them who are seeking a physician. These bureaus will supply to any caller the names of three specialists when a specialized service is requested. Information is also maintained as to physicians who are available during the day or at night and the offices in which they are available. Many of the night calls come from older physicians who request the bureau to send young practitioners on emergency calls. These are samples of specific organizations which are meeting the public demand for emergency medical service.

Actually comparatively few "night calls" are so urgent that harm would result from postponing response until morning. Nevertheless, the patient who suffers pain or the mother who is frightened over a condition in her child that she does not understand is little interested in explanations as to the percentage of emergency calls that are not really emergencies.

Intemperate discussion of this subject has caused some publications to assert that a government medical service would prevent such incidents. These statements are made without knowledge of what actually occurs when government agencies take over medical practice. When the physician is placed on a nonprofessional basis, he is likely to act like other nonprofessional employees.

Any human being who is fatigued or exhausted by long hours of work under conditions of stress and great responsibility will eventually reach a point at which response is difficult. People should understand that the physicians of the United States carried a tremendous burden during the war. The removal of one third of the medical profession from private practice placed enormous stress on those who remained at home. The young men who returned from the war have to work hard to bring themselves up-to-date and they have the same problems of housing, difficulties of securing equipment and making postwar adjustments that occur in every other occupation. These adjustments will be made gradually. Nothing is to be gained by unwarranted acrimonious and intemperate charges of failure to meet what seem to be absolute obligations.

RADIOACTIVE ISOTOPES

In this issue of The Journal Lawrence and associates report 129 cases of chronic myelogenous leukemia treated with radioactive phosphorus.[1] This treatment was developed on the past twenty years' experience of beneficial results from total body roentgen irradiation in this disease.

Radioactive phosphorus (P^{32}) in the form of isotonic sodium mono-hydrogen phosphate was used. The dosage varied from 1 to 2 millicuries once or twice a week up to a total of 40 millicuries administered intravenously over a period of seventy-two days. Extremely wide variations of response occurred. The authors believe that selective action of radioactive phosphorus provides a convenient method of giving generalized irradiation; comfortable life of patients was prolonged in this series, but measurable increases in the duration of life were not observed as compared with patients treated by roentgen ray. Absence of radiation sickness was found to be an advantage. Although they believe radiative phosphorus to be the best known therapeutic agent for chronic myelogenous leukemia, Lawrence and his co-workers say that in no sense does it cure the disease or even completely control it. Further emphasis must be placed on the search for methods other than irradiation for ultimate control of this baffling disease. This report emphasizes the fact that greatest benefit to medicine from present use of atomic isotopes will be the means they provide for more fundamental study of basic physiologic and biologic processes of the animal and human organism.

Results in the purely therapeutic field with radioactive isotopes have thus far not been startling. Radioactive iodine has produced beneficial results in hyperthyroidism and postoperative hyperthyroid recurrence, but it has not been generally effective for cancer of the thyroid. Radioactive phosphorus appears to be the best present therapeutic agent for remitting polycythemia. Certain types of neoplasm have been effectively treated by direct neutron bombardment. Most observers, however, agree that the radioactive isotopes have demonstrated little advantage over roentgen radiation other than selectivity concentration, providing for lower dosage and resultant absence of radiation sickness. Roentgen ray, gamma ray (radium), alpha and beta particle and neutron radiation produce similar effects on body tissues, although their power of penetration varies. Effects of all are most evident on primitive tissues, red and white blood cells, germ cells and cells of neoplastic tissue. Effects on other normal tissues are less but equally comparable.

The terminology associated with Lawrence's paper and others that have been reviewed indicates that physicians must now become acquainted with many new terms and concepts associated with radiation therapy and investigation with radioactive isotopes.[2] Terms such as half life, isotopes, isobars, deuteron bombardment, alpha and beta particles, gamma radiation, and expressions of nuclear formulas are, for the most part, new terms in general medicine. An excellent short review of "Nuclear Energy in Medicine"[3] appears in the advertisement section of The Journal beginning March 22, 1947. To date more than two hundred and fifty isotopes of the known ninety-six elements have been produced, and many of these are available for experimental work. Most promising isotopes for investigative study have been P^{32} (half-life 14.3 days), I^{130} (12.6 hours), I^{131} (eight days), C^{14} (25,000 years), Na^{24} (14.8 hours) and large amounts of heavy water and free deuteron (heavy hydrogen, $_1H^2$). Other useful radioactive isotopes can be developed as needed.

---

Animal experimentation is now under way to determine, through use of radioactive tracer substances, the true biologic and physiologic activity of such elements as phosphorus, iron, sodium, carbon and iodine in the animal body and the manner in which these elements and certain of the organic compounds enter into animal metabolism. In plant metabolism use of tracer substances has already resulted in new understanding of the processes of photosynthesis.[4]

Experimentally produced mutations in plants, Drosophila fly, Neurospora and other lower animal and plant forms indicate that great caution must be exercised in therapeutic and investigative work with radioactive isotopes in human beings. Roentgen rays, gamma rays, beta particle and neutron bombardment have demonstrated their ability to cause break in chromosomal structure and destruction of genes.[5] Broken chromosomes on reuniting lack essential genes, which results in mutation in offspring.[6] Such mutations are represented by malformations or lethal lacks in progeny. They are also hereditarily transmissible. Effects of radiation may be cumulative on chromosomal structure, although there is some evidence that changes are reversible. Experiments with Tradescantia pollen[7] show that effects are twice as great on pollen grains of the haploid chromosomal number which corresponds to the germ cell of human beings. Observers have indicated that mutations brought about by radiation were wholly destructive.[8] Mutations were mainly those which might occur naturally, but artificial radiation greatly accelerates such occurrence. Therefore it is believed that positive or beneficial mutation may normally be brought about by action of chemicals such as colchicine, individual exchanges of thermal agitation and ultramicroscopic accidents of a physicochemical nature, rather than by radiation effect.

H. J. Muller[9] states: ". . . like most species, we are already encumbered by countless undesirable mutations, from which no individual is immune. In this situation we can, however, draw the practical lesson, from the fact of the great majority of mutations being undesirable, that their further random production in ourselves should so far as possible be rigorously avoided. As we can infer with certainty from experiments on lower organisms that all high-energy radiation must produce such mutations in man, it becomes an obligation for radiologists—though one far too little observed as yet in most countries—to insist that the simple precautions are taken which are necessary for shielding the gonads, whenever people are exposed to such radiation, either in industry or in medical practice. And, with the coming increasing use of atomic energy, even for peace-time purposes, the problem will become very important of insuring that the human germ plasm—the all-important material of which we are the temporary custodians—is effectively protected from this additional and potent source of permanent contamination."

These implications warn that therapy or experimentation with radioactive isotopes in human beings during reproductive years may result in destructive biologic changes in progeny.

Current Comment

THE HEART AND BLOOD IN FRESH WATER AND SEA WATER DROWNING

With all the studies that have been made on the various biologic mechanisms involved in drowning, investigators have only recently considered the possibility of a difference in the basic mechanisms of death from drowning in fresh water as contrasted with drowning in salt water. Swann, Brucer, Moore and Vezien in the Physiology Laboratory of the University of Texas Medical Branch[1] have focused attention on the significance of blood concentration and dilution in drowning, depending on whether or not submersion occurs in fresh water or sea water. They find that there is an abrupt and pronounced hemodilution in drowning in fresh water as shown by rapid falls in plasma protein, hemoglobin, chloride and other constituents of the blood. They find the converse, a strong hemoconcentration, in drowning in sea water. Their figures show that in fresh water drowning the blood may dilute to as much as twice its volume. In sea water drowning, however, nearly one third of the water of blood may be removed with rather startling rapidity. These sudden alterations in the concentration of blood might be expected to have significant effects on the heart. The Texas workers find that ventricular fibrillation occurs within three to five minutes after submersion in two thirds of the dogs studied in fresh water drowning. Cardiac fibrillation was not observed in any of the dogs drowned in sea water. During sea water drowning the heart does not fail as quickly as in fresh water drowning. The heart may retain fair functional activity for nearly twice as long in sea water drowning as in fresh water drowning. Apparently, then, there is a greater chance for successful resuscitation in the case of drowning in sea water than in the case of drowning in fresh water.

ORGANIZATION SECTION

Official Notes

HEALTH APPRAISAL OF SCHOOL CHILDREN

A pamphlet outlining standards for determining the health status of school children is now being distributed by the Bureau of Health Education of the American Medical Association.

The brochure is entitled "Health Appraisal of School Children" and is a report of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association. Recommendations as to how the teacher and the nurse may aid the physician with nonmedical portions of the examination are made. Suggestions regarding periodic medical examinations, special examinations and health inspections are also given. The material was edited by Dean F. Smiley, M.D., and Fred V. Hein, Ph.D., of the Bureau of Health Education Staff.

A complimentary copy will be sent to physicians, teachers and public health workers on request.

Washington Letter

(From a Special Correspondent)

March 6, 1948.

Defense Secretary Recommends Reexamination of Pensioned Officers

Defense Secretary Forrestal has recommended to Chairman Elston of the House Armed Services Subcommittee investigating retirement and disability pensions that the more than thirty thousand Army, Navy and Air Force officers who have received tax free disability pensions since 1939 should be reexamined. He urged that the tax exemption be allowed only on the proportion of payments granted for actual disability. Mr. Forrestal pointed out that the basic retirement law was enacted on Aug. 3, 1861, and he remarked that "it is hardly surprising that a law of such antiquity needs revision."

Taft-Fulbright Bill for Department of Health, Education and Security

The Taft-Fulbright bill to create a new federal Department of Health, Education and Security was commended by Oscar R. Ewing, federal security administrator, in an address before an American Legion Child Welfare Conference. He said: "Passage of this bill will mark a great advance in our efforts to achieve the goals of our Chapter of Human Resources." He pointed out that there was cabinet representation for various economic groups, such as farmers and businessmen, but none for Americans as human beings.

Use of Atomic Energy on Blood Ailment Described

Sumner T. Pike, member of the United States Atomic Energy Commission, told participants in Washington Building Congress that radioactive isotopes of phosphorus are being used to treat a rare blood disease, polycythemia vera. He explained that the ailment causes overproduction by the bone marrow of the cells from which red corpuscles are formed, producing an excess of red corpuscles and an extra load on the heart. The isotope goes directly to the cells and curbs their activity, he said.

President Truman Asks Corrective Legislation on Disability Retirement Pensions

Approving changes recommended by Secretary of Defense James Forrestal on disability retirement pensions for officers of the armed forces, President Truman has asked Congress to write new rules. He wrote to Representative Andrews, Republican of New York, and Senator Gurney, Republican of South Dakota, suggesting corrective legislation. They head the House and Senate Armed Forces Committees.

MEDICAL BILLS IN CONGRESS

Local Public Health Units

A bill introduced by Senator Saltonstall, Massachusetts, for himself and Senator Cordon, Oregon, and Senator Hill, Alabama, S. 2189, proposes to enact the "Local Public Health Services Act of 1948." It would authorize an appropriation annually of as much as may be necessary for allotment to the states to assist them in developing and maintaining **local public health units** organized to provide basic full time public health services and in the training of all types of personnel for local public health work. The surgeon general of the United States Public Health Service would be authorized to prescribe by regulation the types of health services which are to be considered basic public health services. State plans must be submitted to the surgeon general for approval.

Federal Aid to Medical Students

Representative King, California, proposes by H. Res. 466 to instruct the House Committee on Interstate and Foreign Commerce to formulate, consider and report to the House appropriate legislation authorizing the Public Health Service to establish and finance **medical scholarships** in recognized medical schools of the United States.

Chiropractors and the Veterans Administration

A bill introduced, by request, by Representative Patterson, Connecticut, would authorize the **appointment of chiropractors** in the Department of Medicine and Surgery of the Veterans Administration.

Social Security Benefits

Representative Kean, New Jersey, proposes by H. R. 5399 to extend the coverage of the federal old age and **survivors insurance** system to include the self employed, employees of nonprofit institutions and agricultural labor, and by voluntary compacts to employees of state and local governments. Another bill, H. R. 5299, introduced by Representative MacKinnon, Minnesota, would extend old age and survivors insurance benefits to certain employees of hospitals.

Miscellaneous

H. R. 1275, introduced by Representative Cole, New York, would authorize the payment of certain **claims for medical treatment** of persons in the naval service. This bill has been reported to the House by the Committee on Armed Services with recommendation that it pass. Another bill, also introduced by Representative Cole, H. R. 5494, proposes to provide **dental treatment** for dependents of naval and marine corps personnel. A bill introduced by Representative Andresen, Minnesota, H. R. 4739, providing for the free importation of **exposed x-ray film**, has passed the House. Representative Dirksen, Illinois, proposes by H. R. 5307 to amend an act providing for the establishment of a hospital center in the District of Columbia in such a manner as to authorize the making of grants to private agencies to enable them to make **surveys and investigations**, and to plan, design, construct, remodel, relocate, rebuild, renovate, extend, equip, furnish or repair hospital facilities in the District of Columbia.

The bill to amend the Public Health Service Act in regard to certain matters of personnel and administration, S. 1454, has passed the Senate and House. It contains an authorization for the appointment of osteopaths as commissioned medical officers in the service.

STATE LEGISLATION

Arizona

Bills Introduced.—H. 2-xxxxx proposes the **creation of the office of director** of the state department of public health and sets forth the eligibility requirements thereof, among which are that the applicant must be a reputable physician licensed to practice in Arizona and a graduate of a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association. H. 4-xxxxx proposes the enactment of an *Arizona hospital survey and construction act* for the purpose of conducting a survey of existing hospital facilities and a construction program for the building of additional needed facilities. The proposal provides for the appointment of an advisory survey and construction council, one member of whom shall be chosen from a panel of four submitted by the Arizona medical association and another member of whom shall be chosen from a panel of four submitted by the Arizona Society of Osteopathic Physicians and Surgeons.

Massachusetts

Bills Passed.—H. 89 passed the house February 18. To amend the medical practice act, it proposes to authorize the board to accept the certificate of the **national board of medical examiners** or the certificate of the national board of examiners for osteopathic physicians and surgeons of the American Osteopathic Association, in place of its own professional examination, provided the applicant has not previously attempted unsuccessfully to secure registration in the state. H. 103 passed the house February 18. Relating to the physical **examination of school children,** it proposes that the board of health shall cause every child in the public schools to be separately and carefully examined at certain intervals to ascertain defects in sight or hearing and other physical defects tending to prevent his receiving the full benefit of his school work. The proposal also would require that a physical record of each child be kept in such form as the department of health may require. H. 107 passed the house February 18. It proposes that certain laws now relating specifically to **gonorrhea and syphilis** shall be made applicable to all venereal diseases. H. 108 passed the house February 18. It proposes the repeal of an existing law requiring **mandatory destruction** of certain laboratory, dispensary and morbidity reports relating to gonorrhea and syphilis at the expiration of five years from the time such reports are made. H. 110 passed the house February 18. To amend the law designating certain **diseases which physicians must report** to the department of public health. It proposes that the department may designate other diseases not specifically mentioned in the statute, which shall be reported by physicians but which shall not thereby be deemed to have been declared diseases dangerous to the public health.

Mississippi

Bill Introduced.—S. 187 proposes regulations providing for treatment and/or assistance in obtaining treatment and diagnosis of **patients having cancer** or suspected of having cancer.

Bill Enacted.—H. 161, approved February 18, amends the 1946 **hospital survey and construction act,** by including nonprofit hospitals and facilities among those organizations eligible for grants in aid.

New Jersey

Bill Introduced.—A. 193 proposes a complete revision of the **workmen's compensation act.**

Bill Passed.—A. J. Res. 2 passed the assembly February 16. It proposes the creation of a commission to make a **survey of all voluntary charitable hospitals** throughout the state to determine what steps can be taken to relieve existing overcrowding and to furnish additional revenue for operating costs to relieve the burden now being carried by the voluntary charitable hospitals.

New York

Bills Introduced.—CCH A. R. 121 proposes the creation of a committee to make a thorough study and investigation into the illegal practice of voluntary **euthanasia of incurable sufferers** in the state and of the law penalizing this practice as murder in order to determine whether amendment of such law would promote the public welfare. A. 1575 and S. 1341, to amend the workmen's compensation law, propose to vest in the **local county medical society** duties now vested in the medical practice committee. A. 1609, to amend the public health law, proposes the creation of a board of **examiners for the practice of massage** and defines massage as the stroking, kneading, tapping or rolling with the hands, or with other instrumentalities, of the human body for hygienic or remedial purposes, for the purposes of relieving, alleviating or reducing affected parts thereof, but shall not include reduction of a fracture or dislocated bone. A. 1731, to amend the public health law, proposes to require every physician to give immediate notice to the health officer of the county, city, town or village of **every case of poliomyelitis** under his care. This proposal would also create a division in the state department of health to be known as the division of infantile paralysis control. A. 1929 and A. 2071, to amend the penal law, propose to require all persons, firms or corporations owning or operating a hospital, clinic, sanatorium or similar institution to have a duly qualified physician or **intern in attendance in its ambulances** when they are being used for the transportation to the institution of any sick or wounded person. S. 1319, to amend the public health law, proposes the creation and establishment of a state hospital with adequate facilities for the diagnosis, **treatment and control of cancer** and allied malignant diseases. S. 1423, to amend the public health law, proposes that immediately **following the birth of a child in a hospital** and prior to the removal of such child from the delivery room it shall be the duty of the physician, midwife or person acting as midwife to cause the footprints of such child and the thumbprints of the mother of such child to be taken in duplicate. S. 839 proposes the creation of a commission to study and survey the prevalence and facilities for the **treatment of infantile paralysis.** S. 942 proposes the creation of a commission to formulate a program for the **eradication of rabies.**

Rhode Island

Bills Introduced.—H. 698, to amend the general laws relating to the **health of school children,** proposes to require every superintendent of schools to cause such examinations of school children as may be necessary for the purpose of guarding against outbreaks of infantile paralysis within the schools of any city or town. H. 706 proposes to authorize the department of health to create and maintain a **division of industrial hygiene** to investigate places of employment and study those conditions which might affect the health of the worker.

South Carolina

Bill Introduced.—H. 1214 proposes to put sulfanilamide, sulfathiazole, sulfapyridine, sulfadiazine, aminopyrine, thyroid and other antifat preparations, together with any other drugs declared to be **"dangerous drugs,"** on a prescription basis.

Bills Passed.—H. 1184 passed the House February 18. It proposes to authorize any person subject to **state income taxes** to deduct all costs of hospitalization, medical services and medicine, on the same basis as is now allowed to persons paying federal income taxes.

Coming Medical Meetings

Alabama, Medical Association of the State of. Mobile, April 15-17. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association of Anatomists, Madison, Wis., April 21-23. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Industrial Physicians and Surgeons, Boston, March 28-April 4. Dr. Frederick W. Slobe, 28 E. Jackson Blvd., Chicago 4, Secretary.

American Association of Pathologists and Bacteriologists, Philadelphia, Jefferson Medical College, March 12-13. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland 6, Secretary.

American Broncho-Esophagological Association, Atlantic City, Chalfonte-Haddon Hall, April 7-8. Dr. Paul H. Holinger, 700 N. Michigan Ave., Chicago 11, Secretary.

American College of Allergists, New York, Hotel Pennsylvania, March 12-14. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Physicians, San Francisco, Civic Auditorium, April 19-23. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Secretary.

American Dermatological Association, Coronado, Calif., April 26-29. Dr. Harry R. Foerster, 208 E. Wisconsin Ave., Milwaukee, Secretary.

American Gastro-Enterological Association, Atlantic City, Claridge Hotel, April 30-May 1. Dr. Dwight L. Wilbur, 655 Sutter St., San Francisco, Secretary.

American Laryngological Association, Hot Springs, Va., April 14-15. Dr. Louis H. Clerf, 1530 Locust St., Philadelphia 2, Secretary.

American Laryngological, Rhinological and Otological Society, Atlantic City, April 7-9. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.

American Orthopsychiatric Association, New York, Hotel Commodore, April 12-14. Nina Ridenour, Ph.D., 1790 Broadway, Rm. 916, New York 19; Secretary.

American Otological Society, Hot Springs, Va., April 12-13. Dr. Gordon D. Hoople, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

American Physiological Society, Atlantic City, March 15-19. Dr. Maurice Visscher, University of Minnesota, Minneapolis 14, Secretary.

American Society for Experimental Pathology, Atlantic City, March 15. Dr. Frieda S. Robscheit-Robbins, 260 Criddenden Blvd., Rochester 7, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 14-19. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.

Arkansas Medical Society, Little Rock, Robinson Auditorium, April 15-17. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

California Medical Association, San Francisco, April 11-14. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 2-5. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Connecticut State Medical Society, Fairfield, April 27-29. Dr. Creighton Barker, 258 Church Street, New Haven, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18 Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Federation of American Societies for Experimental Biology, Atlantic City, March 15-19. Dr. William H. Chambers, Medical Division, Army Chemical Center, Maryland, Secretary.

Florida Medical Association, St. Augustine, Ponce de Leon Hotel, April 11-14. Dr. Robert B. McIver, 111 W. Adams St., Jacksonville, Secretary.

Georgia, Medical Association of, Atlanta, April 27-30. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Louisiana State Medical Society, Monroe, April 12-14. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 27-28. Dr. George H. Yeager, 1211 Cathedral St., Baltimore, Secretary.

Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 10-12. Dr. H. H. Cummings, 2014 Olds Tower, Lansing 8, Chairman.

Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Exec. Secretary.

New England Dermatological Society, Boston, April 14. Dr. G. Marshall Crawford, 1180 Beacon St., Brookline, Mass., Secretary.

New Jersey, Medical Society of, Atlantic City, Haddon Hall, April 26-29. Dr. Earl LeRoy Wood, 315 W. State St., Trenton, Secretary.

Northern Tri-State Medical Association, Findlay, Ohio, April 13. Dr. Don F. Cameron, 247 W. Berry St., Ft. Wayne, Ind., Secretary.

Ohio State Medical Association, Cincinnati, March 30-April 1. Mr. C. S. Nelson, 79 E. State St., Columbus 15, Secretary.

Southeastern Surgical Congress, Hollywood, Fla., Hollywood Beach Hotel, April 5-8. Dr. Benjamin T. Beasley, 45 Edgewood Avenue S. E., Atlanta 3, Ga., Secretary.

Southwest Allergy Forum, Oklahoma City, April 5-6. Dr. Fannie Lou Leney, 1200 N. Walker St., Oklahoma City, Secretary.

Tennessee State Medical Association, Nashville, April 13-14. Dr. W. M. Hardy, 706 Church St., Nashville 3, Secretary.

Texas, State Medical Association of, Houston, Rice Hotel, April 26-29. Dr. Harold M. Williams, 1404 W. El Paso St., Fort Worth, Secretary.

United States-Mexico Border Public Health Association, Laredo, Texas and Nueva Laredo, Mexico, March 20-22. Dr. M. F. Haralson, U. S. Court House, El Paso, Texas, Secretary.

Western Section American Urological Association, Victoria, B. C., Empress Hotel, April 19-21. Dr. Adolph A. Kutzmann, 1930 Wilshire Blvd., Los Angeles, Secretary.

GOVERNMENT SERVICES

NAVY

MEDICAL EXHIBITS

The Bureau of Medicine and Surgery has in preparation an exhibit on "Highlights of Military Surgery in World War II," to be presented at the sixth International Assembly of the International College of Surgeons in Rome, Italy, May 16-23. The surgical advances of World War II are depicted in three phases: (1) "Thoracic and Neurosurgical Advances," to be supervised by Comdr. Morris Weintrob, U. S. N. R. (2) "Rehabilitation of the Amputee," to be supervised by Capt. Henry H. Kessler, U. S. N. R., and to be demonstrated by 14 patients provided by the Italian government, and (3) "Reconstructive Surgery and Maxillofacial and Ocular Prosthesis" will also be under the supervision of Commander Weintrob. After the display in Rome, the Bureau of Medicine and Surgery will use the exhibit as a part of the over-all medical reserve training program in all naval districts in the United States.

The Navy exhibit, "Medicine at Operation Crossroads," presented at the Centennial Session of the American Medical Association in Atlantic City, N. J., last June and at the Texas State Fair in Dallas, was presented also at the New Orleans Graduate Medical Assembly, February 23-26. The exhibit demonstrates the A and B tests at Bikini and the radiologic and damage control safety precautions which were practiced during the tests. These safety precautions proved adequate, as no injury to personnel resulted from either test. The exhibit, presented in three phases, was supervised by Capt. Rupert H. Draeger (MC), Lieut. Comdr. Royce K. Skow (MSC) and Lieut. Carl P. Carlson (MC).

GRADUATE TRAINING

The Advisory Board of the Bureau of Medicine and Surgery at a meeting on February 11 approved the following officers for graduate training:

Lieut. Comdr. John L. Conley (MC), course in electrocardiology at Georgetown University, Washington, D. C.; Lieut. (jg) John M. Jones (MC), residency in internal medicine at the naval hospital, San Diego, Calif.; Lieut. (jg) Byron T. Eberly (MC), residency in otolaryngology at a naval hospital to be designated; Lieut. (jg) William S. Carter (MC), residency in psychiatry at the naval hospital, Philadelphia; Comdr. John F. McMullin (MC), fellowship in psychiatry at the Henry Phipps Institute, Johns Hopkins University, Baltimore, and Comdr. Clinton H. Bagenstose (MC), training in psychoanalysis at the Boston School of Psychoanalysis.

NEW REGULAR OFFICERS

The following naval medical officers were recently transferred from the Naval Reserve to the Regular Navy:

Comdr. Archibald Maurice Ecklund, Naval Hospital, Mare Island, Calif.
Lieut. Comdr. Henry W. Miller, Naval Hospital, Great Lakes, Ill.
Lieut. (jg) Jay Standring Broadbent, Naval Hospital, Long Beach, Calif.
Lieut. (jg) Adolphus William Dunn, Naval Hospital, San Diego, Calif.
Lieut. (jg) Newman Avery Hoopingarner, Naval Hospital, St. Albans, N. Y.
Lieut. (jg) Charles Joseph Molnar Jr., Naval Hospital, Philadelphia.
Lieut. (jg) Ernest Sylvester Redfield Jr., Naval Hospital, St. Albans, N. Y.
Lieut. (jg) Stanley Elwin Reese, Naval Hospital, Long Beach, Calif.
Lieuts. (jg) Mack M. Hill Jr. and John M. Jones, both of Naval Medical Unit, U. S. Public Health Service Hospital, Fort Worth, Texas.

MEDICAL HISTORY OF WORLD WAR II

The Publications Division of the Bureau of Medicine and Surgery is compiling a naval medical history of World War II under the editorial direction of Capt. L. H. Roddis (MC). Capt. E. R. Hering (MC), 2d Marine Division, Camp Lejeune, N. C., and Capt. M. B. Sulzburger, U. S. N. R., of the Skin and Cancer Unit, New York Post Graduate Hospital, will contribute monographs on amphibious warfare and dermatology, respectively. These will be published in pamphlet form prior to the release of the completed volume.

COLLOQUIUM ON RESEARCH

A colloquium on naval medical research was conducted at the Naval Medical Research Institute, Bethesda, Md., February 19 to 21, under auspices of the Medical Sciences Division of the Office of Naval Research.

About two hundred attended. Many prominent persons associated with the nation's leading research laboratories and universities were on the program. Opening remarks were given by the honorable Mr. John M. Brown, Assistant Secretary of the Navy for Air, and by Rear Admiral Paul F. Lee, chief of naval research, U. S. Navy.

MEDICAL LOGISTICS

A didactic course on medical logistics was presented at the Naval Medical School, Bethesda, Md., on February 16-17. All officers of the Navy Medical Corps and Medical Service Corps on duty in this vicinity were invited to attend. Rear Admiral Paul M. Albright, assistant chief, Bureau of Medicine and Surgery for Planning and Logistics, outlined the scope of medical logistics. All lecturers had extensive experience in logistics during the war. This course has been added for the first time to the curriculum of the Naval Medical School.

U. S. S. PETROF BAY CITED

The Presidential Unit Citation has been awarded to the U. S. S. *Petrof Bay* and her attached Air Squadrons "for extraordinary heroism in action against enemy Japanese forces in the air, ashore and afloat. A highly disciplined and superbly coordinated team, the *Petrof Bay* and her Air Squadrons caused serious losses to the enemy . . ., achieving a distinctive combat record which reflects the highest credit on her gallant officers and men and on the United States Naval Service."

GRADUATION EXERCISES

The National Naval Medical Center, Bethesda, Md., held graduation exercises February 28 for students who completed advanced courses at the Naval Medical School and the School of Hospital Administration. The principal speakers were Rear Admiral Lamond Pugh (MC), deputy chief, Bureau of Medicine and Surgery, and Dr. Walter A. Bloedorn, dean of George Washington University School of Medicine.

PERSONALS

Capt. Everett B. Keck (MC) has been ordered to the staff of the commander, Naval Forces, Mediterranean, as fleet surgeon. He is leaving the U. S. Naval Hospital, Brooklyn, where he has served as chief of surgery since March 1946.

Rear Admiral Clarence J. Brown, of the Bureau of Medicine and Surgery, addressed the District of Columbia Medical Society, Washington, D. C., March 3, on "Medical Preparedness in Atomic Defense."

Lieut. Comdr. Thomas E. Shea (MSC) was transferred from the Medical Research Institute, Bethesda, Md., on February 9 to Oak Ridge, Tenn., for a course on radioactive substances under the auspices of the Armed Forces Special Weapons Project, Washington, D. C.

VETERANS ADMINISTRATION

OSTEOPATHS TO WORK WITH VETERANS

Osteopathic physicians now are authorized to provide outpatient treatment within certain limits to veterans with service-connected disabilities. Dr. Paul B. Magnuson, chief medical director of the Veterans Administration, said that "within the limits of practice of the healing art imposed by their respective state licenses, osteopathic physicians, when their services are requested by veterans, may be designated to provide outpatient treatment, on a fee basis, for service-connected disabilities under the same rules and regulations as govern such services by doctors of medicine." Public Law 293, 79th Congress, authorizes the Veterans Administration to hire doctors of osteopathy to work with veterans. All treatment given by doctors of osteopathy or doctors of medicine under the "home town" medical care program must have prior approval of the agency.

REPAIR OF BLIND VETERANS' EQUIPMENT

The Veterans Administration announces that blind veterans who have been issued equipment to aid them in overcoming their handicap may now obtain minor repairs to the equipment without prior approval of the Veterans Administration. Such veterans are receiving prosthetic service cards similar to those used by amputees to obtain minor repairs, and by presenting them to any repair shop in any section of the country, blind veterans will receive repair service up to a limit of $20 without prior approval of the Veterans Administration. Repairs to the following items are authorized under this new plan: typewriters, braille writers, braille watches, radios (excluding batteries), recording equipment and electric razors. The cards will be issued by the prosthetic appliances unit in each regional office; eligible veterans may call for them at their convenience. These cards do not authorize the purchase of new appliances, aids or supplies.

PRESCRIPTIONS FOR VETERANS

About 30,000 pharmacies throughout the country, taking part in the Veterans Administration home-town pharmacy program, filled more than three-quarters of a million prescriptions for veterans during 1947. The veterans were undergoing outpatient treatment for service-connected ailments in Veterans Administration clinics or with private physicians. Under agreements between the Veterans Administration and state pharmaceutic associations in forty-six states, the District of Columbia and Hawaii, private pharmacists have been authorized to fill prescriptions for eligible former servicemen at government expense. Also, during the past year, some two hundred pharmacies in veterans' hospitals, homes and regional offices prepared an estimated four million prescriptions for patients. In addition, they supplied large amounts of routine medicaments to surgical and medical services in the hospitals. Veterans Administration pharmacies have been supplied with the latest in pharmaceutic dispensing equipment and are required to have adequate reference libraries with leading professional journals.

PATIENTS STUDY WHILE BEDRIDDEN

Veteran students in Oklahoma and Arkansas colleges, forced to drop out of school to enter a Veterans Administration hospital for treatment, can continue their studies while bedridden. Under agreements between the colleges and veterans' hospitals in Fayettesville, Ark., and Oklahoma City, the schools send correspondence course material to student-patients in the two hospitals. Members of the Veterans Administration educational therapy staff assist the veterans in preparing their lessons and administer tests and examinations. Periodic lesson reports and examinations are returned to the colleges for grading. Patients who pass their bedside courses receive full credit and, when they are discharged from the hospital, are enabled to continue their education at an advanced level.

MISCELLANEOUS

CARDIAC PATIENTS REHABILITATED

The Federal Security Administrator, Oscar R. Ewing, stated in connection with National Heart Week that through the services of the state-federal program of vocational rehabilitation, 7,000 persons disabled by cardiac disorders had been prepared for and placed in suitable occupations so that they could make their own living.

Michael J. Shortley, director, Office of Vocational Rehabilitation, expressed the belief that greater numbers of sufferers from heart disease will be rehabilitated as the availability of the state-federal services becomes more generally known. He added:

"The 7,000 men and women, all of working age, were rehabilitated between 1943, when the program of vocational rehabilitation for disabled civilians was expanded, and 1947. . . . Their comeback has been achieved through state vocational rehabilitation agencies in each of the forty-eight states, the District of Columbia, Alaska, Hawaii and Puerto Rico, which serve not only persons with cardiac disorders, but also those with other types of disabilities."

The services provided by the state rehabilitation agencies include: Thorough physical examinations to determine extent of disability; medical, surgical, psychiatric and hospital care, if necessary, to reduce or remove the disability; hearing aids, artificial limbs, braces, eyeglasses and the like, to increase work ability; counsel and guidance to select the right job; training for employment; placement on the right job, and follow-up to make sure that the worker and the job are properly matched.

Physical examinations, counsel and guidance, training, placement and follow-up are without cost to the individual; other necessary services may be provided from public funds to the extent that the disabled person is unable to meet them with his own resources.

ATOMIC ENERGY FELLOWSHIPS

The selection of candidates for fellowships provided by the Atomic Energy Commission to train qualified persons in atomic medicine and biology will be carried out by the National Research Council. The program is expected to continue for about five years, and about seventy-five fellows will be selected each year from physicians and doctors of philosophy and biologic sciences. The fellowships will be for two years. The program calls also for one hundred fellows without advanced degrees to take one year of training in health physics. The commission desires these fellows from all geographic areas in the country, but they will have some latitude in selecting the institution for their training. The commission, it is said, will have plenty of jobs in its own installations after this training, but the fellows who complete the course will not have to agree to work for the Atomic Energy Commission.

SEMINAR ON RAT CONTROL

The Fish and Wildlife Service of the Department of the Interior held a seminar on rat control in New York February 18, preliminary to the national urban rat control campaign which will be held during March and April as a part of the President's Emergency Food Conservation Program. The damage caused by rats in this country is estimated at $2,000,000,000 a year, half of which is in the destruction of food. The seminar was planned to aid the many industries that have rat control problems. Among those present was Hamilton M. Warren, vice president of the National Carbon Company and chairman of the National Committee on Rat Control, and experts from the Fish and Wildlife Service.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

X-Ray Unit for State Health Department.—The Arizona State Department of Public Health has recently taken delivery on a bus-type x-ray unit that has been on order for about two years. It started its tour of the state in Santa Cruz County, adjoining the Mexican border, about March 1.

ARKANSAS

Cancer Fund Campaign.—The University of Arkansas School of Medicine is conducting a campaign for $50,000 to provide adequate facilities for diagnosis and treatment of cancer. The fund will be used principally to purchase equipment for the department of radiology, an additional therapy unit, and to augment personnel and supplies. Figures demonstrating the increase in cancer in the state were reported by heads of the departments of radiology, pathology and gynecology.

CALIFORNIA

Personals.—The degree of doctor honoris causa has been conferred on Wendell M. Stanley, Ph.D., Nobel laureate in chemistry, by the rector of the Sorbonne at ceremonies at the University of Paris, France. Dr. Stanley, recently appointed to the faculty at the University of California, Berkeley-San Francisco, was not present at the ceremonies, his degree being received by a representative of the U. S. Department of State on his behalf.——Dr. Jacob C. Geiger, director, San Francisco Department of Public Health, has been appointed by the Bureau of Naval Operations to assist in the development of a public ealth program in Guam.——Dr. James N. De Lamater, assoiate professor of medicine, has been appointed assistant dean f the University of Southern California School of Medicine, Los Angeles, to succeed Dr. Anson P. S. Hoyt, who has held he position for six years. Dr. De Lamater came to Southern California in 1945. As a commander in naval service during World War II, he was head of the department of epidemiology t the Naval Medical Center in Washington, D. C., and while n the Southwest Pacific was director of the disease control rganization of the Seventh Naval Fleet. Dr. Hoyt will do acteriologic research in the tuberculosis control division of the U. S. Public Health Service with laboratories located at the Barlow Sanatorium, Los Angeles. He will continue to serve he university as professor of bacteriology in the medical school, with which he has been affiliated since 1931.

FLORIDA

Hospital Honors Drs. Peek and Watt.—The staff and board of trustees of Munroe Memorial Hospital, Ocala, honored Drs. Eugene G. Peek and Harry F. Watt for their many years of service to the hospital at a dinner recently. Dr. Peek was cited for his outstanding contributions to organized medicine in the state and his many activities in civic and state organizations. Dr. Watt's record in World War I, his service as Ocala's health officer and his participation in medical and service organizations were reviewed.

Dr. Roland Decorated by China.—The Chinese government has awarded to Dr. Paul S. Roland, Miami Beach, the Special Breast Yon Hui with ribbon and diploma in consideration of services achieved in conformity with conditions laid down in article 6 of the regulations governing decorations and awards. Lieutenant Colonel Roland was formerly chief liaison officer, 42nd Regiment, 14th Division, new 6th Army of China. He was taken prisoner by the Japanese, was on the "Bataan march of death" and later in Japanese prison camps. At great personal risk he cared for the sick, and he is said to have saved many lives under extremely difficult circumstances.

ILLINOIS

Diabetes Increasing in State.—Statistics released by the state director of public health February 18 show an increase in diabetes in the state. Deaths to Nov. 1, 1947, numbered 2,284, setting a rate of 33.4 per hundred thousand population as against a rate of 31.5 for the comparable period of 1946, when 2,103 deaths were reported. There were 1,581 deaths in 1926, 2,293 in 1936 and 2,541 in 1946. Diabetes ranks eighth as a cause of death in Illinois.

Chicago

The Koessler Fellowship.—The Jessie Horton Koessler Fellowship of the Institute of Medicine of Chicago for the aid of research will be available on Sept. 1, 1948. The stipend is $500 a year with the possibility of renewal for one or two years. Applications will be received until July 1, 1948 and should be sent in quadruplicate to Dr. Paul R. Cannon, chairman of the committee, 950 East Fifty-Ninth Street, Chicago 37.

Moorehead Memorial Library.—The Frederick B. Moorehead Memorial Library in Oral and Maxillofacial Surgery will be established at the University of Illinois College of Dentistry. A gift of $2,864 from the University of Illinois Dental Alumni Association represents the first instalment of funds for the project. The library is to contain books, manuals and current periodicals. Dr. Moorehead served as the first dean of the University of Illinois College of Dentistry and as head of the department of oral surgery from 1912 until his death in August 1944.

Chicago Surgical Society Annual Prize.—The Chicago Surgical Society awards annually a prize for a manuscript describing experimental work in experimental and clinical surgery. The following criteria are used by the judges: (1) the paper must represent original work of one man aided by associates, but not necessarily based on a completely original idea; (2) illustrations must be original and not borrowed from someone else's correlated work; (3) the paper must never have been read or printed anywhere as submitted in its final form, and (4) the diction and simplicity of the presentation as given in the written copy must ever remain a large factor in its value. Papers should be submitted without identification marks, accompanied by a sealed envelope bearing on its outside the title of the paper, and containing within it the name and address of the author. These should be in the hands of the secretary, Dr. Charles B. Puestow, 30 North Michigan Avenue, Chicago, not later than March 15, 1948.

Conference and Broadcast on Alcoholism.—The first Industrial Conference on Alcoholism under the direction of Dr. Anton J. Carlson, emeritus professor of physiology, University of Chicago, and Dr. Andrew C. Ivy, vice president at the University of Illinois, will be held at the Morrison Hotel, Chicago, March 23. Among the speakers will be: Elvin M. Jellinek, Sc.D., Yale University, New Haven, Conn.; Dr. George H. Gehrmann, Wilmington, Del., medical director of E. I. Du Pont de Nemours & Company; Dr. John L. Norris of the Eastman Kodak Company, Rochester, N. Y.; Dr. David Slight, superintendent, Division of Veterans' Rehabilitation Centers, Chicago; Dr. Robert V. Seliger of Johns Hopkins University, Baltimore, and Dr. Robert E. Maupin of the Keeley Institute, Dwight, Ill. The Northwest Reviewing Stand radio program over WGN, Chicago, March 21, 10:30 a.m. central standard time, will broadcast a program devoted to the subject of alcoholism. Participants will be: Dr. Ivy; James H. Oughton Jr., director of the Keeley Institute; a member of the Chicago group of Alcoholics Anonymous, and Mrs. M. Colvin of the W. C. T. U.

INDIANA

Personals.—Dr. Neslen K. Forster, Hammond, president of the Indiana State Medical Association in 1945, has disposed of his practice and moved to LaJolla, Calif.

Discontinue Section Meetings.—The council of the state medical association has voted to discontinue section meetings at the 1948 annual session in Indianapolis, October 26-28. Each of the six sections will provide one speaker for the general scientific assembly.

Josiah Lilly Dies.—Josiah K. Lilly, chairman of the board of directors of Eli Lilly & Company, pharmaceutical manufacturers, died in Methodist Hospital, Indianapolis, February 8, aged 86. Mr. Lilly was president of the firm from 1898 until 1932 and had been a trustee of Purdue University, Lafayette, for ten years.

Society Celebrates Hundredth Birthday.—The Indianapolis Medical Society celebrated its hundredth anniversary February 24. Speakers included Lieut. Gov. Richard James; Mayor Al Feeney of Indianapolis; Dr. Cleon A. Nafe, president of the state medical association; Thomas A. Hendricks, Chicago, secretary, Council on Medical Service, American Medical Association, and, from Indianapolis, Dr. William N. Wishard Jr., Dr. Edgar F. Kiser and Mrs. Otto H. Bakemeier, president of the society's woman's auxiliary. Twenty-two past presidents were guests of honor. Dr. Bert E. Ellis, president of the society, presided. The society when organized Feb. 26, 1848 had twenty-one members; the membership today is nearly nine hundred.

IOWA

Field Secretary for State Society.—The Iowa State Medical Society has employed Mr. Donald L. Taylor to act as field secretary to relate the activities of the society more closely to the activities of individual members. He will visit meetings of county medical societies where desired, talk to individual physicians to learn their problems and questions and convey their inquiries and wishes to the central office and through it to the officers or committees involved. Mr. Taylor reported for duty February 1.

KANSAS

Public Relations in Finney County.—The Finney County Medical Society began a publicity program for the year by contracting with the *Garden City Telegram*, a newspaper, for advertising in the Saturday issue. Two members of the society prepare the copy. No schedule was set up for the year, so the copy may treat any medical subject that local conditions might indicate. Health hints, vaccination programs, chest x-ray surveys and general instruction on disease are among the subjects to be presented.

Tumor Diagnostic Clinics.—Since January 1947, when the Committee on Control of Cancer of the Kansas State Medical Society launched a program to establish tumor diagnostic clinics in all Kansas hospitals meeting the standardization requirements of the American College of Surgeons, eighteen of the state's twenty tumor clinics have been set up. The Kansas Division of the American Cancer Society, Inc., offered last year to pay each tumor clinic meeting the minimum standards $500 at the end of two months of successful operation. Since that time the cancer society has offered the clinics $500 at the beginning of the second year of operation.

MASSACHUSETTS

Grant for Training Nuclear Scientists.—A $250,000 grant for atomic research and training of nuclear scientists has been made to the Massachusetts Institute of Technology by the Texas Company. This work will be carried on primarily in the laboratory for nuclear science and engineering, which will coordinate its efforts with the departments of physics; chemistry; chemical, electrical and mechanical engineering; metallurgy, and biology for maximum interchange of information. One important phase of the program is the training of competent nuclear scientists and engineers by allowing them to conduct pioneer studies and thus gain invaluable experience.

Laboratories of Sanitary Science.—The William Thompson Sedgwick Laboratories of Sanitary Science have been added to the department of civil and sanitary engineering at the Massachusetts Institute of Technology, Boston. The new laboratories of sanitary engineering, sanitary chemistry and research, and sanitary bacteriology and research are designed to meet modern educational procedures in teaching sanitary engineering and to provide a thorough knowledge of the chemical and biochemical reactions which take place in the treatment of water, sewage and industrial wastes. William E. Stanley, professor of sanitary engineering, is in charge of the new laboratories.

MISSOURI

Vision Testing of School Children.—In a study sponsored by the National Society for the Prevention of Blindness, the U. S. Children's Bureau and the Missouri Division of Public Health, evaluation will be made of instruments used to test vision of school children. About 1,200 children in twenty elementary schools in St. Louis will be given six different types of tests by teachers, nurses and a technician. Following this all children will receive an eye examination by oculists at Washington University Eye Clinics. Cooperating in this study, in addition to the Washington University School of Medicine, is the St. Louis City Board of Education.

State Medical Meeting in St. Louis.—The Missouri State Medical Association will hold its ninetieth annual session at the Jefferson Hotel, St. Louis, March 14-17 under the presidency of Dr. Morris B. Simpson, Kansas City. Out of state speakers include:

William F. Mengert, Dallas, Texas, Overtreatment of Eclampsia.
Lewis S. Jordan, Granite Falls, Minn., Diagnosis of Tuberculosis in Rural Areas.
Charles G. Johnston, Detroit, Signs and Symptoms of the Acute Abdomen.
Bayard T. Horton, Rochester, Minn., Headache.
Thomas E. Smith, Dallas, Texas, Common Proctologic Conditions.
Henry T. Ricketts, Chicago, Treatment of Diabetes.
Charles H. Johnston, Des Moines, Iowa, Supportive Procedures.

The Tuesday afternoon program will be taken up with a symposium on pediatrics. At the past presidents' banquet at 7 p.m. March 15, Dr. Edward L. Bortz, Philadelphia, President of the American Medical Association, will speak on "Medicine's New Frontiers." The dinner for presidents and secretaries of county medical societies will be Sunday at 6 p.m.

MINNESOTA

Dr. Balfour Honored.—Dr. Donald C. Balfour, director emeritus of the Mayo Foundation, Rochester, was awarded a Certificate of Merit from the President of the United States at a ceremony in Balfour Hall, Mayo Foundation House, Rochester, February 5. Rear Admiral F. L. Conklin, medical officer of the Ninth Naval District with headquarters at Great Lakes, Illinois, made the presentation on behalf of the President. The Certificate, signed by President Truman and bearing the presidential seal, reads as follows: ". . . The President of the United States awards this Certificate of Merit to Dr. Donald C. Balfour for outstanding fidelity and meritorious conduct in aid of the war effort against the common enemies of the United States and its Allies in World War II . . ."

NEBRASKA

University Opens Student Health Center.—The University of Nebraska opened its new Student Health Center February 2. The center is housed in a two story, war surplus officer's barracks, which has been remodeled into a temporary hospital of twenty-six beds and is staffed with eight full time nurses, three part time nurses, a part time dietitian, two cooks, one x-ray technician, one laboratory technician and two orderlies. Eight Lincoln physicians are serving part time and seven are on a consulting staff. Dr. Sam I. Fuenning is the director.

NEW YORK

Mr. O'Connor Honored.—Basil O'Connor, president of the American Red Cross, has been honored by the British government as an Associate Knight of the Order of St. John of Jerusalem for "humanitarian work of great proportions." The Order originated in the eleventh century to provide hospital care for Crusaders reaching Jerusalem and later spread throughout Europe. The English branch is principally concerned with hospital and ambulance service.

Public Health Fellowships.—Dr. Herman E. Hilleboe, New York state health commissioner, announces the availability of fellowships for young physicians interested in entering public health as a career. The fellowships are for two years or less, depending on the qualifications of the applicant, and carry with them a stipend of $3,600 per year. In addition, necessary travel and other expenses are paid as well as tuition at a school of public health. Information may be obtained by writing to Dr. Franklyn B. Amos, New York State Department of Health, Governor Alfred E. Smith State Office Building, Albany 1, New York.

Rochester Academy Awards.—Two awards open to physicians and nurses of the eleven counties of the Rochester area have been added to those made each year by the Rochester Academy of Medicine. Certificates and $100 will be given to a physician for a thesis contributing to knowledge of medical practice as related to hospitals and to a registered nurse for a thesis contributing to the knowledge of nursing. The awards will be made by the academy at its annual meeting May 3. Papers should be submitted to the Awards Committee, Academy of Medicine, Rochester, N. Y., before April 1.

New York City

Society News.—At the February meeting of the local chapter of the International Spanish Speaking Association of Physicians, Incorporated, at the Waldorf-Astoria Hotel, a symposium was presented on arthritis.

Dr. Lull to Address Kings County Medical Society.—Dr. George F. Lull, Chicago, Secretary and General Manager of the American Medical Association, will speak March 16 at a meeting of the Kings County Medical Society, Brooklyn, on "Current American Medical Association Activities."

Clinic to Serve All Age Groups.—The Kate Depew Strang Prevention Clinic in Memorial Hospital has made its services available to men, women and children of all ages. The first examination for teen-agers was held February 6, and this group will be served each succeeding Friday. A year ago the clinic inaugurated special examinations for children from birth to 14 years of age.

Industrial Psychiatric Fellowship.—A pioneer program to train psychiatrists for the industrial relations and labor field will be inaugurated at Cornell University with an industrial psychiatry fellowship offered in the School of Industrial and

Labor Relations. The Carnegie Corporation has made a supporting grant. The fellowship will be awarded to a physician with experience in psychiatry and will provide two years of training at the school. In addition to classroom study in basic industrial and labor relations courses, the fellow will receive training in human relations work in a plant, labor union or government office.

Health Bulletin on Cancer Control.—Social and public health workers throughout the country will receive copies of a health bulletin for industry prepared by the Brooklyn Cancer Committee and distributed by the National Publicity Council for Health and Welfare Services. The bulletin issued recently in cooperation with the Brooklyn Industrial Health Committee was chosen by the council for inclusion in its publicity packets. The bulletin was a feature of the regular service to industry introduced fifteen months ago by the Brooklyn Cancer Committee. Each month a health pinup goes to five thousand industrial firms in Brooklyn for placement on factory and office walls to inform workers about cancer control.

Postgraduate Lectures.—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged the following graduate lectures. The St. Lawrence County Medical Society will hear Dr. Wardner D. Ayer, Syracuse, speak on "Neurology in General Practice" March 11 at 12: 30 p.m. at Potsdam. He will deliver the same lecture to members of the Jefferson County Medical Society at 8 p.m. at Watertown. The programs arranged for the Madison County Medical Society will be given Thursday evenings at 8: 30 at the Hotel Oneida, Oneida.

March 18, Dr. Walter F. Bugden, Syracuse, Diagnosis and Treatment of Surgical Lesions of the Esophagus.
March 25, Dr. Robert O. Gregg, Syracuse, Surgery of the Stomach.
April 1, Dr. Albert D. Kaiser, Rochester, N. Y.; Rheumatism in Childhood.

A symposium on rheumatic fever has been arranged for the Oneida County Medical Society at the Hotel Utica, April 13 at 8 p.m. Dr. T. Duckette Jones, Boston, will speak on "Diagnosis of Rheumatic Fever"; Dr. Leo M. Taran, Brooklyn, "Hospital and Convalescent Care of the Rheumatic Fever Patient," and Dr. J. G. Fred Hiss, Syracuse, "Community Programs." On April 6 the Schenectady County Medical Society will hear Dr. George N. Papanicolaou, New York, speak on "Use of Cell Smears in the Early Diagnosis of Cancer," at the Ellis Hospital, Schenectady, 8:30 p.m.

OHIO

State Medical Meeting at Cincinnati.—The annual meeting of the Ohio State Medical Association will be held at the Netherland Plaza and Hotel Gibson, Cincinnati, March 30-April 1, under the presidency of Dr. Ralph L. Rutledge, Alliance. Guest speakers at the general sessions on March 30 and 31 at 3:15 p.m. will be:

Alan R. Moritz, Boston, Investigation of Deaths in the Interests of Public Safety.
Dallas B. Phemister, Chicago, Treatment of Selected Cases of Bone Sarcoma by Resection and Bone Transplantation.
F. Bayard Carter, Durham, N. C., Conservatism in Surgery of the Uterus and the Ovaries.
Merrill C. Sosman, Boston, Pitfalls in Roentgen Examination of the Gastrointestinal Tract.
Harold G. Wolff, New York, Headache Mechanisms.

One of the features of the meeting will be the series of instructional courses to be given daily from 1:30 to 3 p.m. at the Netherland Plaza. Six different courses each day of the meeting will be conducted as panel discussions and will provide informal instruction on clinical problems in everyday practice. Admission will be only by cards, which may be obtained in advance on application to the Columbus office, Ohio State Medical Association. There will be no charge; attendance will be limited to one hundred persons or fewer. At the annual banquet March 31, the program will be 100 per cent entertainment. Sectional meetings are scheduled from 9 a.m. to noon each day on medicine; anesthesiology; obstetrics and gynecology; general practice; public health and preventive medicine; eye, ear, nose and throat; surgery; nervous and mental diseases, and pediatrics.

Annual meetings of the Ohio State Radiological Society and the Ohio Chapter, American College of Chest Physicians will be held March 31.

PENNSYLVANIA

Meeting of Allergy Society.—The Central Pennsylvania Allergy Society will meet at the Yorkshire Hotel, York, April 1. The subjects include treatment of bronchial asthma, cytology of nasal secretions with special reference to allergic diseases, headache from the allergic point of view and the role of antihistaminic drugs.

Pittsburgh

Conference on Mental Health.—The Western State Psychiatric Institute will hold its third annual Coordinating Conference at the institute in Pittsburgh April 1, with research in mental health as the conference's theme. Among those on the program are: Dr. Paul I. Yakovlev, Yale University School of Medicine, New Haven, and the state hospital, Middletown, Conn.; Dr. Erich Lindemann, Massachusetts General Hospital and Harvard University School of Medicine, Boston; Dr. Lothar B. Kalinowsky, New York Psychiatric Institute and Hospital and associate research professor at Columbia University, New York; Dean Ruth Kuehn of the School of Nursing, University of Pittsburgh; Carney Landis, Ph.D., principal research psychologist of the New York State Psychiatric Institute and Hospital, and Helen Witmer of the Smith College School of Social Work. At the dinner meeting Dr. William Menninger, Topeka, Kan., will speak on "Research in Mental Health in the National Perspective." All professionally interested persons in Pennsylvania and vicinity are invited.

SOUTH CAROLINA

Personal. — Dr. John M. Preston, Columbia, has been appointed director of the state board of health, division of tuberculosis control, succeeding Dr. Franklin L. Geiger, resigned.

State Association Publishes News Letter.—In November the first South Carolina Medical Association *News Letter* was mailed to all members of the association. Through the *News Letter* information regarding current activities and news relating to the profession and its welfare can be turned over to the members of the association more rapidly than through the pages of the state journal. The association has also changed the content and concept of the quarterly Bulletin with its December issue by changing the name of the publication to *Auxiliary Bulletin*, since it has become the joint enterprise of the association and the Woman's Auxiliary.

VIRGINIA

Personal.—Dr. Jacques P. Gray, dean of the School of Medicine of the Medical College of Virginia, Richmond, 1942-1947, has joined the staff of Parke Davis & Company as medical consultant to the sales promotion division.

New Department of Anesthesiology.—A new department of anesthesiology has been opened at the Medical College of Virginia, Richmond, to offer training to physicians who desire to specialize in anesthesiology. Dr. William E. Pembleton, Hartford, Conn., has been named by president William T. Sanger to serve as director of the new department.

WEST VIRGINIA

License Revoked.—The license of Dr. Elmer Groves Kesler, Williamsburg, to practice medicine in West Virginia was revoked January 12 by the Public Health Council at a meeting in Charleston, on the grounds of "habitual use of narcotic drugs."

Annual Cancer Meeting.—The annual meeting of the West Virginia Cancer Society will be held in Charleston March 19, and at the annual dinner that evening Dr. Charles S. Cameron, New York, medical director of the American Cancer Society, Inc., will be the speaker. At the meeting of the board of directors and the state executive committee, officers for the new year will be elected, including a new secretary of the executive committee to succeed Dr. Paul R. Gerhardt, who is now director of the state bureau of cancer control, Albany, N. Y. Work shop meetings will be held the morning of March 20. Participation in the meeting is limited to those who contributed as much as $5 during the past year to funds for cancer control.

Conference of Secretaries.—The annual Secretaries Conference, discontinued during World War II, is scheduled for the Daniel Boone Hotel at Charleston March 14. Local secretaries, presidents of component societies and officers and members of the council will be present. The meeting will get under way at 10 a.m. and will adjourn at 4 p.m. The following program has been arranged:

L. Fernald Foster, secretary, Michigan State Medical Society, Bay City, Mich., Public Relations.
Wingate M. Johnson, Winston-Salem, N. C., Postgraduate Education for the General Practitioner.
Theodore Wiprud, executive director and secretary of the Medical Society of the District of Columbia, Washington, D. C., Planning Medical Society Programs.
Newman H. Dyer, state health commissioner, Charleston, Public Health Administration.

A roundtable discussion will follow the address of each speaker; in addition, there will be a roundtable discussion of problems of administration that concern local societies and the headquarters offices of the state medical association.

GENERAL

Societies for Experimental Biology.—The Federation of American Societies for Experimental Biology will meet in Atlantic City, N. J., March 15-19. The federation is composed of the American Physiological Society, American Society of Biological Chemists, American Society for Pharmacology and Experimental Therapeutics, American Society for Experimental Pathology, American Institute of Nutrition and American Association of Immunologists. The scientific sessions, ninety-six in number, will be held in the Atlantic City Convention Hall. Headquarters will be at Chalfonte-Haddon Hall.

Conference of Society for the Study of Sterility.—The American Society for the Study of Sterility, Eastern Section, will hold its second annual conference on the Clinical Aspects of Fertilization and Impregnation in Human Reproduction at the Hotel Pierre, New York, March 13 beginning at 9 a.m. The conference will consist of four panel discussions, two of which will be devoted to the male and two to the female. Moderators will be John MacLeod, Ph.D., New York; Dr. Oswald S. Lowsley, New York; Carl G. Hartman, Ph.D., Urbana, Ill., and Dr. Robert L. Dickinson, New York.

Banquet to Honor General Hawley.—To mark the beginning of its sixth year of service, the National Council on Rehabilitation will honor Gen. Paul R. Hawley, recently retired medical director of the Veterans Administration, at a banquet at the Waldorf-Astoria Hotel, New York, on March 19. Charles P. Taft, chairman, committee of sponsors, will preside. Dr. Henry H. Keesler, president of the council, in commenting on the reason for choosing General Hawley for the honor, said: "General Hawley's reorganization of medical services, on which the physical restoration of the disabled veteran is based, constitutes a unique contribution to the field of rehabilitation."

Congress on Reproduction.—All papers to be presented before the first International Congress of Physiology and Pathology of Animal Reproduction and Artificial Insemination should be sent to the secretary general of the congress, 17 Via Fratelli Bronzetti, Milan, Italy, before March 31, 1948. Papers must be followed by a summary not exceeding one hundred words. The congress will be composed of the following sections: (1) biologic problems of animal reproduction; (2) breeding problems of animal reproduction; (3) pathologic problems; (4) artificial insemination of animals, and (5) legislation and organization problems of artificial insemination and of animal reproduction.

Resolution Concerning Pooled Plasma.—The following statement was approved by the Committee on Medicine, Division of Medical Sciences, National Research Council, February 9, as a modification of the resolution submitted by the Subcommittee on Liver Diseases: "Since numerous cases of hepatitis, some fatal, have resulted from transmission of hepatitis virus in human *pooled* plasma, the Committee on Medicine strongly recommends that dried or liquid *pooled* plasma not be used until a satisfactory means of sterilizing such products is found. Exceptions may be made in patients with severe burns or in mass emergencies where sufficient whole blood is not available. It is further recommended that persons known to have had jaundice at any time should not be used for blood donors."

Annual Meeting of Allergists.—The American College of Allergists will hold its fourth annual session at the Hotel Pennsylvania, New York, March 12-14, under the presidency of Dr. Hal M. Davison, Atlanta, Ga. The longer papers to be given at the scientific sessions include:

March 12, Alexander S. Wiener, Brooklyn, Rh Factor in Immunologic Reactions.
Richard H. Overholt, Brookline, Mass., Common Surgical Problems Which Often Masquerade as Asthma.
March 13, Philip D. McMaster, New York, Anaphylactic Shock in Mice Induced by a Traceable Colored Antigen.
Otto Loewi, New York, Transmission of Nervous Impulse.
March 14, Edward C. Rosenow, Cincinnati, and Bayard T. Horton, Rochester, Minn., Bacteriologic Studies in Multiple Sclerosis.
Henry P. Wagener and Dr. Horton, Rochester, Minn., Retrobulbar Neuritis: Treatment with Histamine.

A panel discussion on "Otolaryngologic Phases of Allergy" will be held Sunday afternoon. The informal banquet will begin at 7;30 p. m. A postconvention pleasure trip free of charge has been arranged.

Poliomyelitis Reports for 1948.—The 1948 edition of "Facts and Figures About Infantile Paralysis," a publication of the National Foundation for Infantile Paralysis, is now available to physicians and public health workers. Statistics on the disease, revised yearly, are gathered from the United States Public Health Service, state health departments and various other sources. Statistics furnish information on age and sex distribution, case rates, crippling conditions and mortality. For the first time this publication includes data on the disease in foreign countries. Copies of the booklet (number 59) may be secured free of charge by writing Education Service, the National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

International Leprosy Congress.—The fifth International Leprosy Congress, sponsored by the government of the Republic of Cuba and the International Leprosy Association, will meet at Valdés Rodríguez School in Havana, Cuba, April 3-11, under the presidency of Dr. Herbert W. Wade, Culion, P. I. The National Organizing Committee has extended and shall extend special invitations to universities, official bodies, dermatologic or leprologic associations or persons interested in attending. Application for invitations to attend should be made to the secretary of the committee, Dr. Ismael Ferrer, Calzada de Columbia y 8va Marianao, Cuba.

The congress will take up the determination of the value of the new sulfone drugs in the treatment of leprosy and will discuss the approval or modification of the new South American classification of leprosy. The scientific work will be handled by five committees: therapeutics, classification, epidemiology, research and social assistance. Official languages of the congress will be Spanish, French, English and Portuguese.

Birth Rate at Record High.—Although the monthly birth rate in the United States has declined from the postwar peak of 29.5 per thousand population in December 1946, the birth rate for the entire year of 1947 established a new postwar peak. According to the Feb. 16, 1948 *Monthly Vital Statistics Bulletin* (National Office of Vital Statistics, Federal Security Agency) the provisional birth rate for 1947 was 25.9 per thousand population, about one-ninth higher than the corresponding rate of 23.3 for 1946. The monthly rates for the first eight months of 1947, although below the December 1946 peak, were so much higher than the rates for the corresponding months in 1946 that the annual rate for 1947 is actually greater. It is the highest annual rate recorded since the birth registration area was established in 1915. The number of registered live births for 1947 was about 3,720,000 as compared with the final figure of 3,288,672 for 1946. These birth rates have not been adjusted to the number of women at the child-bearing ages; they show merely the number of births per thousand population, which includes males and females of all ages.

INDIA

Smallpox in Calcutta.—The *New York Times* reported February 12 that 406 persons died from smallpox in Calcutta during the week that ended February 7. Latest mortality figures are thirteen times higher than those for the week ending December 6, when smallpox was declared epidemic. Almost 200,000 persons were vaccinated the week of February 2.

Marriages

Marshall de Graffenried Ruffin, Washington, D. C., to Miss Laura Monteen Brannen of Fort Lauderdale, Fla., Nov. 22, 1947.

Albert Ira Robbins, New York City, to Miss Shirley Constance Berlin of Brookline, Mass., Dec. 21, 1947.

Charles C. Wannamaker, Orangeburg, S. C., to Miss Wilna Betty Poe of Greenville, Oct. 25, 1947.

Stuart S. Bederman, Chicago, to Miss Miriam Jacobs of Elgin, Ill., in Honolulu, Hawaii, January 22.

William Edward Sandrock to Dr. Rachel Shipps Rice, both of Rochester, N. Y., January 17.

Edward Gipstein to Miss Edith Joyce Glassenberg, both of New London, Conn., Oct. 26, 1947.

Robert S. Monk, Boise, Idaho, to Miss Nan Helen Brockway of Waukesha, Wis., Aug. 16, 1947.

Avrohm Jacobson to Miss Shirley Applebaum, both of Washington, D. C., January 3.

Nard Lair, Dallas, Texas, to Miss Clara Lee Hethcoat at Sulphur Springs, February 14.

Edward Lloyd Seretan to Miss Enid Sheila Stollerman, both of New York, Aug. 31, 1947.

William Carl Beck, Sayre, Pa., to Miss Jane Murray of Waverly, Dec. 13, 1947.

Michael Ladd, New York, to Miss Anne Pratt of Bridgewater, Conn., January 2.

Deaths

William Edward Bannen ⊕ La Crosse, Wis.; born in Boscobel, Wis., in 1881; Northwestern University Medical School, Chicago, 1908; specialist certified by the American Board of Urology, Inc.; member of the House of Delegates of the American Medical Association in 1916 and from 1929 to 1936; fellow of the American College of Surgeons; past president of the Wisconsin Urological Society; medical examiner on the Selective Service Board during World War I; recently retired from the Wisconsin National Guard with the rank of lieutenant colonel; in 1934 awarded the Silver Beaver in recognition of his services in the Boy Scouts; member of the city and county boards of health; chief preceptor at the University of Wisconsin in Madison; affiliated with St. Francis Hospital; died in Rochester, Minn., Nov. 20, 1947, aged 67, of cirrhosis of the liver.

Arthur Wells Elting ⊕ Albany, N. Y.; born in South Cairo, N. Y., Oct. 16, 1872; Johns Hopkins University School of Medicine, Baltimore, 1898; retired July 1, 1937 as professor of surgery at the Albany Medical College; member of the founders group of the American Board of Surgery; past president of the American Surgical Association; member of the Society of Clinical Surgery; fellow of the American College of Surgeons; served in France during World War I; for many years chief surgeon of the Delaware and Hudson Railroad Corporation; senior vice president of the Albany Savings Bank; served on the staff of the Albany Hospital; died January 2, aged 75, of multiple myeloma.

Benjamin Peter Farrell, New York; Long Island College Hospital, Brooklyn, 1904; emeritus professor of orthopedic surgery at Columbia University College of Physicians and Surgeons; specialist certified by the American Board of Orthopædic Surgery, Inc.; member and formerly vice president of the American Orthopedic Association; member of the American Medical Association; fellow of the American College of Surgeons; affiliated with the Englewood (N. J.) Hospital and the Presbyterian Hospital; served as surgeon in chief of the New York Orthopedic dispensary and Hospital; died in Stamford, Conn., Dec. 27, 1947, aged 77, of mesenteric thrombosis.

Frank Matthew Conlin ⊕ Omaha; born in 1883; Rush Medical College, Chicago, 1907; specialist certified by the American Board of Internal Medicine; professor of clinical medicine, University of Nebraska College of Medicine; past president of the Omaha-Douglas Counties Medical Society; member of the state board of medical examiners and board of directors of the American Diabetic Association; affiliated with the Nebraska Methodist Hospital and Deaconess Home, Bishop Clarkson Memorial, University of Nebraska, St. Catherine's and the Douglas County hospitals; died Dec. 15, 1947, aged 64, of acute coronary thrombosis.

William Hadley Richardson ⊕ Colonel, U. S. Army, retired, Harrisburg, Pa.; born in Ohio, Sept. 6, 1876; Western Reserve University Medical Department, Cleveland, 1901; fellow of the American College of Surgeons; served as lieutenant (jg) Ohio Naval Militia from 1903 to 1905; commissioned as a first lieutenant in the medical corps of the U. S. Army in June 1907; served during World War I; retired as a colonel April 30, 1940; past president of the Medical Association of the Isthmian Canal Zone; served with the state board of health as chief of the division of sanatoriums until 1944; died January 15, aged 71, of coronary thrombosis.

Arthur Smith Chittenden ⊕ Endicott, N. Y.; born 1872; Johns Hopkins University School of Medicine, Baltimore, 1900; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association in 1926; served as vice president of the Medical Society of the State of New York; consulting surgeon at Charles S. Wilson Hospital in Johnson City and Ideal Hospital; formerly attending surgeon at Binghamton State Hospital; consultant to the Binghamton (N. Y.) City Hospital, where he died January 6, aged 75, of arteriosclerotic heart disease and bronchiectasis.

William Tarun ⊕ Baltimore; born in 1870; University of Maryland School of Medicine, Baltimore, 1900; formerly on the faculty of his alma mater; member of the American Academy of Ophthalmology and Otolaryngology, Association for Research in Ophthalmology, and American Ophthalmological Society; fellow of the American College of Surgeons; chief of clinic, University Hospital; ophthalmologist and otologist, James Lawrence Kernan Hospital and Industrial School for Crippled Children in Baltimore and the Rosewood State Training School at Owings Mills; died Nov. 21, 1947, aged 77, of carcinoma of the lung.

Oscar Arthur Axelson, Youngstown, Ohio; University of Michigan Medical School, Ann Arbor, 1930; member of the American Medical Association; awarded the Bronze Star for meritorious service and five campaign stars during World War II; died Dec. 6, 1947, aged 44, of coronary thrombosis.

Thomas A. Baltz, Pomona, Mo.; St. Louis College of Physicians and Surgeons, 1896; died in St. John's Hospital, Springfield, Dec. 8, 1947, aged 74, of carcinoma of the lung.

William Hamlin Banks ⊕ Mifflintown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1889; charter member and past president of the Juanita County Medical Society; medical examiner for the county draft board during World War I; for many years county medical director and surgeon for the Pennsylvania Railroad; died Dec. 24, 1947, aged 85, of mesenteric thrombosis.

George William Benitz, Wathena, Kan.; Baylor University College of Medicine, Dallas, 1922; member of the American Medical Association; county coroner and health officer; died Nov. 15, 1947, aged 68, of heart disease.

Martin A. Blanton, Mosheim, Tenn. (licensed in Tennessee in 1906); member of the American Medical Association; died Dec. 17, 1947, aged 74, of coronary occlusion.

Albert Liddell Callery, Port Huron, Mich.; Trinity Medical College, Toronto, Canada, 1897; past president and secretary of St. Clair County Medical Society; member of the American Medical Association; assistant director of St. Clair County Department of Health; city health officer; affiliated with Port Huron Hospital; died Dec. 3, 1947, aged 62, of coronary occlusion.

Francis Albion Carmelia ⊕ Medical Director, U. S. Public Health Service, retired, Norristown, Pa.; Jefferson Medical College of Philadelphia, 1911; entered the U. S. Public Health Service on March 15, 1913; served as assistant surgeon general; died in Montgomery Hospital, Dec. 15, 1947, aged 58, of heart disease.

Horace H. Darlington ⊕ Concordville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1879; died Dec. 16, 1947, aged 90, of senility.

Albert Benson Deering ⊕ Boone, Iowa; Northwestern University Medical School, Chicago, 1898; fellow of the American College of Surgeons; died Dec. 12, 1947, aged 73, of coronary sclerosis.

Daniel Meeker Denman, Cincinnati; Cincinnati College of Medicine and Surgery, 1881; member of the American Medical Association; for many years probate court alienist; died Dec. 26, 1947, aged 90, of coronary occlusion.

William E. Drisdale, Santa Fe, N. Mex.; Rush Medical College, Chicago, 1893; died recently, aged 80.

William Edgar Fallis, Louisville, Ky.; Hospital College of Medicine, Louisville, 1907; member of the American Medical Association; formerly on the faculty of the University of Louisville School of Medicine; for many years on the staff of the Deaconess Hospital, where he died Dec. 11, 1947, aged 61, of coronary occlusion.

Harry Lawrence Farmer ⊕ Cleveland; Baylor University College of Medicine, Dallas, Texas, 1918; specialist certified by the American Board of Radiology, Inc.; member of the American Roentgen Ray Society, [illegible] of North America and the American [illegible] served on the staff of Huron Road Hos[illegible] Ohio; died Dec. 6, 1947, aged 52, of coronary thrombosis.

James William Farrior, Warsaw, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the American Medical Association; served during World War I; died Dec. 16, 1947, aged 65, of cerebral thrombosis.

Mark Lance Fleming, Orlando, Fla.; Cornell University Medical College, New York, 1901; general medical superintendent of the department of hospitals in New York City from 1930 to 1936, when he retired; at one time superintendent of the Bellevue Hospital in New York; died Dec. 7, 1947, aged 67, of coronary occlusion.

William Alexander Jack ⊕ Washington, D. C.; Howard University College of Medicine, Washington, 1896; served on the faculty of his alma mater and on the staff of the Freedman's Hospital; died Dec. 31, 1947, aged 74, of chronic cardiorenal vascular disease.

Henry Lincoln Johnson, Brunswick, Maine; Columbia University College of Physicians and Surgeons, New York, 1912; served as college physician of Bowdoin College; died Dec. 3, 1947, aged 61, of coronary thrombosis.

Raymond Child Jones, Ashby, Mass.; University of Vermont College of Medicine, Burlington, 1902; member of the American Medical Association; died at his winter home in Mount Dora, Fla., Dec. 2, 1947, aged 66, of coronary thrombosis.

Harry S. King, Grosse Ile, Mich.; McGill University Faculty of Medicine, Montreal, Canada, 1892; formerly adviser at the Juvenile Court in Detroit; died in the Harper Hospital, Detroit, in December 1947, aged 76, of renal insufficiency following an operation for benign hypertrophy of the prostate.

George N. Lake, Pleasant Lake, Ind.; Fort Wayne College of Medicine, 1902; died Nov. 24, 1947, aged 71, of coronary occlusion.

Charles Edward Lane ⊕ Poughkeepsie, N. Y.; New York Homeopathic Medical College, 1883; past president of the city council; affiliated with St. Francis Hospital and the Vassar Brothers Hospital, where he died Dec. 27, 1947, aged 92, of arteriosclerotic heart disease.

Clifford McCalmont Lane ⊕ Pittsburgh; Johns Hopkins University School of Medicine, Baltimore, 1918; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; served in France during World War I; for many years on the staff of the Allegheny General Hospital, where he died Nov. 27, 1947, aged 56, of coronary occlusion.

Sebastian Lang ⊕ New York; Eberhard-Karls-Universität Medizinische Fakultät, Tübingen, Württemberg, Germany, 1921; affiliated with Lenox Hill Hospital and St. Francis Hospital, where he died Dec. 7, 1947, aged 55, of carcinoma of the transverse colon.

Luther Middleton Latham, Coral Gables, Fla.; Medical College of Alabama, Mobile, 1892; died Oct. 31, 1947, aged 77.

Morris Julius Lavine ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1919; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of America; on the staff of the Onondaga County Hospital, Onondaga; died Nov. 8, 1947, aged 50, of carcinoma of the rectum.

Walter John Leaman ⊕ Leaman Place, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; died Nov. 11, 1947, aged 73.

David Barnard Lepper, Bluefield, W. Va.; Harvard Medical School, Boston, 1902; member of the American Medical Association; for many years county health officer; captain in the medical corps of the U. S. Army during World War I; died Dec. 8, 1947, aged 72, of aplastic anemia.

James Webster Loughlin ⊕ Newcastle, Maine; Medical School of Maine, Portland, 1900; for many years health officer for third district; served during World War I; died Dec. 22, 1947, aged 76, of aplastic anemia and hypertrophy of prostate.

Walter James Lowrie ⊕ North Braddock, Pa.; Medico-Chirurgical College of Philadelphia, 1908; served on the staff of the Braddock (Pa.) General Hospital; a director of the First National Bank; died Nov. 15, 1947, aged 64, of coronary occlusion.

Marcus Henry Lynch, Manning, Iowa; Drake University Medical Department, Des Moines, 1911; at one time employed by the government as examining physician for the Civilian Conservation Corps camps in Arkansas; served as physician for the Rock Island Railroad; died Nov. 25, 1947, aged 65, of heart disease.

Tilden T. Manzer, Seattle; University of Louisville (Ky.) School of Medicine, 1913; member of the American Medical Association; fellow of the American College of Surgeons; member of the staffs of the Swedish and Kings County hospitals; died Nov. 24, 1947, aged 58.

Thurman Francis McAllister, Coshocton, Ohio; Ohio State University College of Medicine, 1934; member of the American Medical Association; past president of the Coshocton County Medical Society; served overseas during World War II; affiliated with the Coshocton Memorial Hospital; died Nov. 11, 1947, aged 38, of rheumatic endocarditis.

Edwin S. Miller, Scranton, Pa.; Maryland Medical College, Baltimore, 1900; died Nov. 26, 1947, aged 82.

Edward Wright Peet ⊕ Pomona, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 18[illegible]0; served during the Spanish-American War and World War I; an Affiliate Fellow of the American Medical Association; formerly member of the seventy-first regiment of the New York National Guard; at one time on the staff of Roosevelt Hospital in New York; died January 3, aged 85, of uremia.

William Robert Perkins ⊕ Washington, D. C.; Columbian University Medical Department, Washington, 1901; also a graduate in pharmacy; affiliated with the Doctors, Columbia, Emergency, Homeopathic, Sibley, George Washington, Garfield and Children's hospitals; died in Doctors Hospital Dec. 9, 1947, aged 71, of acute myocardial infarction.

William Jerdone Pettus ⊕ Senior Surgeon, U. S. Public Health Service, retired, Charleston, S. C.; Medical College of Virginia, Richmond, 1884; fellow of the American College of Surgeons; joined the U. S. Public Health Service as an assistant surgeon in 1886, serving later as an assistant surgeon general; died in Roper Hospital Dec. 28, 1947, aged 84, of cerebral thrombosis and arteriosclerosis.

William Stewart Philp ⊕ Pasadena, Calif.; McGill University Faculty of Medicine, Montreal, Canada, 1889; died Nov. 29, 1947, aged 81.

John Arnold Reese ⊕ Attleboro, Mass.; Tufts College Medical School, Boston, 1908; fellow of the American College of Surgeons; served during World War I; chief surgeon, Sturdy Memorial Hospital; died Dec. 10, 1947, aged 62, of coronary thrombosis.

Harold Irwin Reynolds, Athens, Ga.; Johns Hopkins University School of Medicine, Baltimore, 1912; member of the American Medical Association; fellow of the American College of Physicians; served during World War I; consulting physician to the University of Georgia; affiliated with St. Mary's Hospital and Athens General Hospital, where he died recently, aged 60, of chronic lymphatic leukemia.

Joseph Harrison Robinson Jr., Hamlet, N. C.; Howard University College of Medicine, Washington, D. C., 1944; served an internship at Lincoln Hospital in Durham, N. C.; died Nov. 24, 1947, aged 27.

Richard William Robinson ⊕ Laconia, N. H.; Yale University Medical School, New Haven, 19[illegible]0; past president of the New Hampshire Medical Society; served during World War I; affiliated with the Laconia Hospital; died in Boston Nov. 17, 1947, aged 54, of coronary heart disease.

Richard Frederick Rowse, Beaver, Pa.; University of Pittsburgh School of Medicine, 1943; served an internship at the Western Pennsylvania Hospital and a residency at the Mercy Hospital in Pittsburgh; served during World War II; affiliated with Rochester (Pa.) General Hospital; died recently, aged 33, of an accidental gunshot wound.

Joseph A. Sinclitico, Lawrence, Mass.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1901; died Nov. 30, 1947, aged 73.

Horace Adam Skidmore, West Mansfield, Ohio; Starling Medical College, Columbus, 1902; also a graduate in pharmacy; died Nov. 18, 1947, aged 73, of a hip fracture suffered in a fall.

Alva Ellsworth Stonecipher, Pasadena, Calif.; Western Pennsylvania Medical College, Pittsburgh, 1888; died Dec. 9, 1947, aged 84, of carcinoma of the sigmoid.

Elijah Van Camp ⊕ Battle Creek, Mich.; Northwestern University Medical School, Chicago, 1903; affiliated with Leila and Community hospitals; served during World War I; life member of Michigan State Medical Society; died Dec. 5, 1947, aged 72, of coronary thrombosis.

George Bickford Van Doren ⊕ Watertown, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1900; for many years city health officer; served during World War I; affiliated with the House of the Good Samaritan and Mercy Hospital; died Nov. 28, 1947, aged 74, of coronary thrombosis.

Bernhard Henry Vollertsen, Carneys Point, N. J.; University of Michigan Homeopathic Medical School, Ann Arbor, 1918; died in Presbyterian Hospital, New York, Nov. 11, 1947, aged 55.

Walter Alva Weed ⊕ Orlando, Fla.; Maryland Medical College, Baltimore, 1905; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America and the American College of Radiology; served as secretary of the Florida Radiological Society; an officer during World War I; affiliated with Orange General Hospital, where he died Dec. 2, 1947, aged 64, of carcinoma of the right cheek.

Robert Davis Wiswall ⊕ Vancouver, Wash.; University of Oregon Medical School, Portland, 1897; died Nov. 10, 1947, aged 77.

Elizabeth Raymond Withrow, Corsicana, Texas; University of Arkansas School of Medicine, Little Rock, 1939; member of the American Medical Association; died Nov. 30, 1947, aged 39, of burns received when her home caught fire.

National Medical Service

There is at present a period of stalemate in the government plans for a national medical service in Australia. The British Medical Association is standing firm on eight principles: (1) opposition to a full time salaried service; (2) freedom from control in professional matters; (3) freedom for the patient to choose his own physician; (4) freedom of the physician to practice where and in the way he thinks best; (5) adequate medical representation on controlling bodies; (6) freedom from political interference; (7) a fee-for-service form of payment, and (8) a stable guaranteed fund to finance the service.

The government has made no definite statement on the principles which underly any proposed plan, but views expressed by the minister of health on various occasions indicate that: (1) private practice would be eliminated; (2) control and direction would be exercised over physicians in the service; (3) the government would not appoint nominees of the British Medical Association to the central controlling body, and (4) a fee-for-service method of payment is not favored. The chief bone of contention between the physicians and the government has to do with the method of payment for services. The minister for health, at the last discussion, agreed to hear arguments in favor of the fee-for-service method. The British Medical Association committees of all states of Australia, especially Western Australia, have been active in preparing a case for submission.

It is not expected that the government will take action to implement any national medical service in the near future. After many months of stormy sessions in parliament, a bill to nationalize the trading banks was passed late in 1947. Now the government has to face a legal challenge which will absorb its attention for the next few months. In the meantime plans for a national medical service are undergoing a partial eclipse. It is known that high officials of the commonwealth health department are continuing the preparation of plans, but this has been going on for ten years without much definite result. Two important factors are operating. First, there is no public demand for a national medical service. In general the people are reasonably satisfied with the present combination of private practice and public hospitals, even though all agree that there is scope for improvement. The lay press does not favor a national medical scheme, if only because further extension of nationalization may lead to application of the principle to its own sphere. Second, the labor government, which is driving for a national service, is losing political ground. Only two of the six states, Queensland and New South Wales, can now be regarded as strongholds of the labor movement. The other four states have either a nonlabor government or such a weak majority of the labor party members that they are politically impotent.

It is again proposed by the government that pharmaceutical benefits (free medicine) be introduced early this year. This announcement is not taken seriously, as similar statements have been made at intervals since the legislation was passed. Recently there have been no official conferences with chemists or physicians to attempt to solve the outstanding difficulties. The present medical attitude to "free medicine" is that the federal council of the British Medical Association in Australia could not advise members of the medical profession in Australia to use the government prescription forms and formulary. The association has taken legal opinion regarding the government's constitutional power (as extended by the referendum) in regard to the obligations of the medical profession. The legal opinion is that the services of medical practitioners cannot be compelled. The power under the constitution, as amended, is not a power to regulate medical services but only to legislate to provide such services without power to compel any person to render them.

Centenary of Royal Melbourne Hospital

On March 15, 1948 the Royal Melbourne Hospital will celebrate its centenary. As part of the plan to celebrate this historic occasion, the Committee on Management, in conjunction with the Medical Staff, has arranged for a scientific session to take place from March 1 to 10. Dr. William Evans, eminent London cardiologist, will lecture during the session. Through the courtesy of the Royal Australasian College of Surgeons, Sir Hugh Cairns, Nuffield professor of neurosurgery at Oxford University, will also lecture.

Discussions About Artificial Abortion

Article 218 of the German Criminal Code, enacted in 1871 and still in effect, makes abortion punishable. The law admits of no exception. In practice, however, the medical indication has been recognized for a long time.

In 1927 an important decision was rendered by the German Supreme Court at Leipzig, by which a state of emergency is recognized when, after a careful weighing of all medical circumstances, an abortion is performed in a case of "present danger" to the pregnant woman, which cannot be overcome by other means. "Present danger" is defined as a state of affairs which in the normal course of events will with certainty lead to danger of life or a serious impairment of health, unless preventive measures are taken. An abortion performed in such an emergency is not considered a violation of the law.

The war and the postwar period brought about not only an increased number of abortions but also gave a new impetus to discussions about the application of Article 218. These discussions are promoted by the following factors: the bad food and housing situation which has increased the demand for a social indication; the occurrence of many cases of rape; a checkered variety in the administration of justice brought about by the splitting up of Germany into four zones and of these four zones into individual provinces, and, finally, anticipated changes in legislation.

MEDICAL INDICATION

In the discussions there is no question about the generally recognized permissibility of interruptions of pregnancy on medical grounds. However, while one should expect under present conditions that physical impairment would be the main reason for permitting abortions, there is in fact an ever increasing percentage of psychiatric diagnoses advanced for that purpose. Professor Scheid, Hamburg, stresses that justified psychiatric indications are rare. This holds true even for most cases of psychosis, because they are not often aggravated by pregnancy. Only such cases of psychosis as occur for the first time during pregnancy, the puerperium or lactation may be considered an indication for terminating pregnancy. Cases of paralysis or epilepsy will seldom justify an abortion. Questionable is the justification of an interruption based on reactive depression, the psychiatric diagnosis most frequently advanced. Even suicidal tendencies in such cases call, according to the author, for treatment in an institution rather than abortion.

SOCIAL INDICATION

While most authors agree that medical indications may be modified by social circumstances, they draw a sharp dividing line between such indications and those on purely social grounds, for which the demand has increased with the poor food and housing situation. In contrast to the ideas prevailing in the western zones, the Central Administration of Public Health in the Soviet zone stated recently that, under the existing living conditions, the interruption of a pregnancy on social grounds is permissible. The need must be stated by a committee consisting of physicians and persons experienced in public welfare; the pregnancy must not be older than three months, and the woman must have been informed of the dangers involved. The chief of German administration of justice in that part of Baden which belongs to the French zone stated in December 1945 that no social or ethical indications can be recognized.

INDICATION OF RAPE

In July 1946 the minister of justice in Greater Hesse (American zone) issued a regulation providing that the interruption of a pregnancy is not punishable if performed by a licensed physician who, after a thorough examination of all circumstances, has come to the conviction that the pregnancy is the consequence of a criminal act. The previously mentioned chief of administration of justice in Baden (French zone) stated that no indication on the grounds of rape can be recognized. Several authors in the western zones, notably Spiegler (Frankfurt) emphasize the danger of recognizing such indication inasmuch as it is almost impossible to prove that a pregnancy is the consequence of rape when no other evidence is available than the statement of the woman herself. An important factor in weighing the evidence ought to be whether or not the incident was reported immediately after the alleged occurrence or only after the woman has become convinced that she is pregnant. In several cases in which interruption was declared permissible on the basis of the previously mentioned Hessian regulation, a more thorough interrogation and examination proved that, in view of the stage of pregnancy, the alleged rape could not have been its cause. Cases in which there was sufficient evidence to prove rape have not often resulted in pregnancy. Moreover, the number of rape cases has decreased sharply since the beginning of 1946. Sometimes such incidents have been advanced as a medical indication for interruption on psychiatric grounds. The difficulties in such decisions have been discussed previously.

EUGENIC INDICATION

A clearly eugenic indication for abortion is not accepted anywhere. Amazingly, even the Nazis did not make it legal. Spiegler stresses that even in the case of Huntington's chorea with its dominant gene the offspring will be ill only in 50 per cent of the cases if only one parent has the disease. In all other mental diseases the probability that the child will inherit it is less than 50 per cent if only one parent is ill. In schizophrenia only 53 per cent of the children acquire the disease if both parents are afflicted (quoted from Bumke). With one parent ill, the probability is not more than 10 per cent. The same holds true with other mental diseases. Therefore it appears that of all combinations only Huntington's chorea in both parents would provide a scientifically valid reason for interruption of pregnancy.

Acute Dilatation of the Intestine Following Faulty Nutrition

Brandt, of Detmold, describes 7 cases of acute dilatation of the intestine following faulty nutrition which were seen in the second half of 1946 in a hospital which formerly averaged 1 case of megacolon per year. Early in 1947 he treated 3 more patients with a similar condition. All patients had eaten large amounts of calorically poor, fermenting vegetable food immediately preceding their illness. The attack started acutely and developed into a complete ileus within twenty-four hours. The most characteristic sign in these cases is an enormous distention of the abdomen, comparable only to advanced ascites. If the general condition is not too bad, conservative treatment may be tried first, consisting of a high rectal tube, neostigmine and 80 per cent sodium chloride solution intravenously. If there is no success within one or two hours at the most, operation is imperative. The results are good if no torsion has set in—if it has, prognosis becomes bad. On opening the abdominal wall the enormously distended sigma, rarely the transverse colon, protrudes. If there is danger of bursting, the intestine must be punctured immediately. Otherwise, the largest available tube, preferably a stomach tube, is inserted rectally and pushed up high enough to permit the gas to escape. Necessary auxiliary manipulations on the intestine are generally easy enough. Success is usually immediate. As to the cause of the attack, the author assumes that a slight torsion or constipation leads to a certain stagnation, proximal to which fermentation develops rapidly. It is obvious that there must be a predisposition for such attacks, namely, a megasigma or megacolon transversum, but the patients had seldom had any prior intestinal troubles. The author is of opinion that this predisposing factor is also a result of the faulty carbohydrate-rich diet of the last years.

Medical Meetings

Psychiatrists and Neurologists.—On April 26 and 27, 1947 a meeting of the psychiatrists and neurologists of the British-occupied zone took place at Bremen. The seventy-three participants constituted themselves the Association of Psychiatrists and Neurologists of Northwestern Germany, with Kehrer (Münster), Pette (Hamburg) and Schneider (Gütersloh) as members of the board. A special committee was appointed to draft new legislation in the field of eugenics and to formulate a program for youth welfare and the treatment and care of war veterans who suffer from cerebral and neural injuries. The meeting dealt also with the problem of euthanasia and with the problems of legal responsibility of criminals, for the purpose of giving expert opinions before British and American Military Government Courts. A resolution was passed stressing that the formation of the association should not encroach on the activities of existing smaller associations in the same field and should not exclude or prejudge decisions of any future, nationwide association.

Gynecologists.—From Oct. 15 to 18, 1947, a scientific meeting of the gynecologists in the Soviet zone of occupation took place in Berlin. Several guests from the western zones were present. Jung (Berlin) delivered an interesting lecture on the influence of nutritional deficiency on pregnancy and childbirth. These effects are amazingly small, as has also been noted during and after the first world war. Toxemias of pregnancy have decreased by 50 per cent because of the lack of proteins. The birth weight is more often than formerly below 3,000 Gm. (6 pounds 11 ounces). There are 5 per cent more premature babies. There is a decidedly bad influence on lactation. In the field of gynecology nutritional deficiencies play a more important role, as can be expected in the field of illnesses as contrasted with the normal functions of pregnancy and childhood. Martius (Göttingen) spoke on radiation therapy and reported on the opening of an institute of nuclear physics in Göttingen. On the last day of the meeting, operations were performed at all gynecologic clinics ad demonstrandum for the guests.

Psychiatrists.—On Sept. 11, 1947 the first international congress of psychiatrists was opened in Tübingen (French zone), in which representatives from England, France, Switzerland and the United States participated.

Miscellaneous

Some time ago the daily press reported that the rector of Leipzig University had declared that the medical faculty will have to close by the end of the summer term. The reason given was a statement made by the dean of the medical faculty that he could not further assume responsibility for the training of medical students if the teaching staff would not be immediately strengthened by the hiring of new, qualified teachers.

ITALY

Vaccination with Anatuberculin

At a meeting of the Medical Academy "Filippo Pacini" at Pistoja, Professor Gaetano Salvioli discussed the fate of those vaccinated with killed tubercle bacilli. For about fifteen years there has been employed in Italy a prophylactic antituberculous vaccination by means of killed germs (Petragnani's anatuberculin) which was designated "Petragnani-Salvioli's vaccination by infection." The method consists in producing four infectious lesions on the skin by inoculation with considerable doses of formaldehyde-killed Mycobacterium tuberculosis. The four lesions, like other tuberculous lesions, may have a course of several months' duration. Histologically they consist of tuberculous tissue, and they leave a permanent scar. Thus a persistent allergy is caused (the percutaneous allergy disappears first, while the intradermic will last longer) and a specific resistance is established. The defense depends, according to Salvioli, on the course of this artificial primary tuberculous infection. This defense has been demonstrated by studies on children aged 6, 7 or 8 years, vaccinated at birth, who immediately afterward were exposed to contagious contacts without any postvaccinal precautions such as are taken after BCG vaccination. In general these children were poor and had suffered considerably from the war.

The Vaccine Center of Bologna carried out the vaccination by infection on 5,700 infants in the course of eight years. In the vaccinated subjects who were controlled at the age of 7 years the mortality was lower than the average mortality at this age in the city of Bologna. With Mantoux's test always performed seven years after the vaccination, the allergy was positive in 90 per cent of the vaccinated children.

Among those living with tuberculous members of their families (55 cases), about three fourths (41 cases) did not manifest, either on roentgenologic examination or by an allergic response, a past infection. One fourth of the patients, according to the skin reaction and the results of the roentgenologic examination, apparently had overcome a latent infection; in a few subjects the infection was still acute, although they had a measurable degree of allergy and were in good physical condition.

In some groups of siblings living with tuberculous contacts the health of a vaccinated child was compared with that of a nonvaccinated sibling. In one third of the vaccinated children a past infection was demonstrated, but apparently they were in good health and their resistance was more favorable than that of the nonvaccinated siblings, all of whom presented symptoms of infection or of tuberculous disease. There were 3 fatalities among 4,500 vaccinated children residing in Bologna. All 3 children died before reaching 1 year of age and had contracted the infection definitely early in their lives and in the pre-antiallergic period.

According to Professor Salvioli, the results obtained with the killed vaccine surpass those obtained with the living BCG vaccine and are due to the course of the vaccine-induced infection and to the characteristic properties of vaccine produced with killed germs of anatuberculous nature. The attenuated germ is perishable, while the killed germ is stable and deprived of the stimuli which contribute to the digestion of the bacilli. In Sweden Professor Rinvik, by using killed Bacillus Calmette-Guérin for subcutaneous injections, has succeeded in obtaining an immunizing preparation for Koch's phenomenon which could not be obtained in persons vaccinated with living bacilli taken orally. The allergy obtained with killed BCG organisms has been demonstrated by Rinvik and by Manclouf in France.

Professor Salvioli stated his conviction that preference should be given to the killed vaccines because they are more active and nonperishable and since by using them the troubles caused by the living BCG vaccine can be avoided regardless of the route of introduction. For efficient vaccination an infectious vaccine-induced lesion of the Salvioli type is required, and this may be produced by inoculation of the vaccine into the skin.

After Professor Salvioli's report Dr. Magni, director of the hospital for abandoned children in Pistoja, reported his experience with BCG vaccine; his results showed that the children vaccinated by this method had manifestations of general dystrophia and presented a diminished resistance to infections.

Professor Fiore, director, pediatric clinic, University of Pisa, pointed out the importance of Professor Salvioli's report. He predicted a new era in the practice of antituberculous vaccination. Professor Salvioli in answering the various speakers recalled that since 1927, when Professor Magni reported on the reduction of resistance in persons vaccinated with BCG, an accentuation of the specific resistance has not been demonstrated in these vaccinated persons. With reference to Professor Buonomini's opinion that research should be performed to find an antigen and a type of vaccination which would eliminate the evolution of the vaccinal infection, Professor Salvioli recalled the statement made during the discussion by Professor Grassi, who, perceiving the principle involved in vaccination by infection, agreed that it is necessary to produce in the subject of vaccination this insignificant and innocuous tuberculous disease and that this may be obtained with Salvioli's vaccine.

BRAZIL

(From Our Regular Correspondent)

São Paulo, Dec. 26, 1947.

Plague in Brazil

Plague is not uncommon in Brazil. Drs. João de Barros Barreto and Almir de Castro, of the Oswaldo Cruz Institute, have tabulated in three year periods the 2,610 cases which occurred from 1934 to 1945.

The federal government in 1936 started a systematic antiplague program. The disease is now limited to the so-called Brazilian northeast with the state of Pernambuco as the major focus where, since 1934, 40 to 50 per cent of the total cases have occurred.

From the cases recorded during the 1941-1945 period, Drs. Castro and Barreto showed that more than 50 per cent of the 1,610 confirmed cases were in persons over 50 years of age. Except for 9 cases of pneumonic plague and 13 cases of septicemic plague, all the patients showed the bubonic form.

The case fatality rate in the period under consideration was 26 per cent, or only 12 per cent if patients who did not receive any treatment are excluded. The administration of sulfonamide drugs in place of antiplague serum reduced the case fatality rate.

Drs. Barros Barreto and Almir de Castro found evidence suggesting that Mus musculus may also play a part in the spread of the disease. Reference is made to twenty-six observations of wild rodents naturally infected with plague in the states of Ceará, Pernambuco and Alagôas.

Xenopsylla cheopis is the predominant species of flea in the tropical section of the country. Its density decreases as the latitude goes higher, inversely to what happens with Xenopsylla brasiliensis, which is the most prevalent in the temperate southern state of São Paulo.

Correspondence

THE PAPANICOLAOU TEST FOR UTERINE CANCER

To the Editor:—In The Journal of the American Medical Association, January 31, page 331, the editorial on "The Papanicolaou Test for Uterine Cancer" concludes with the paragraph:

"Recently a manufacturer of laboratory equipment has promoted the sale of the materials for the Papanicolaou test together with a hundred slides of various types of cells found in cervical smears. The firm cannot, however, sell the most important ingredient—a competent pathologist to study the specimen promptly after it is secured from the patient. The offer implies that special training is not necessary to secure and to examine the specimen. The indiscriminate use of this test will result in more harm than good."

We wish to take exception to the statement, "the offer implies that special training is not necessary to secure and to examine the specimen." Our advertisement (adv. p. 54) in the Dec. 27, 1947 issue of The Journal very prominently displays in a boxed-off area heading the advertisement and under the main title the following statement: "IMPORTANT! The taking of smears, scrapings, etc. *in preparation* for staining and diagnosis is a relatively simple matter and can be done by any trained doctor or technician—the staining and diagnosis should be done *only by those prepared by intensive training in the technic.*" This statement is carried in practically all of our advertising except perhaps the first few hundred sheets of literature which we put out, and which we subsequently withdrew. The literature which is now obsolete will soon be replaced by literature which we have some weeks ago arranged to have read by Dr. George N. Papanicolaou and approved by him. We also plan to send the same literature to Dr. J. Ernest Ayre, Royal Victoria Hospital, Montreal, Canada, and possibly to the New York office of the American Cancer Society.

To quote further, the editorial states: "The firm cannot, however, sell the most important ingredient—a competent pathologist to study the specimen promptly after it is secured from the patient." Our organization and I in particular have done more than what we consider to be a reasonable amount of work in the direction of obtaining information on competent pathologists or doctors who can stain and diagnose the smears. We have in the past limited our recommendations to men who were unquestionably qualified to stain and diagnose the tests. These are, of course, Dr. George N. Papanicolaou at the Cornell Medical College; Dr. J. Ernest Ayre at the Royal Victoria Hospital, Montreal, Canada; Dr. Herbert F. Traut at the University of California Medical School; Dr. Olive Gates at the New England Deaconess Hospital in Boston, and one or two others. Frankly, we have hesitated to recommend any one because we are not in a position, generally speaking, to evaluate the qualifications of a diagnostician to perform such a test. The men who have been mentioned are unquestionably qualified.

Since we became interested in the instrumentation for this Papanicolaou test, we have contacted Dr. Papanicolaou to request information on qualified diagnosticians. Such a list was not available from Dr. Papanicolaou. We then contacted Dr. Austin V. Deibert at the U. S. Public Health Service in Bethesda, Md., and he wrote us on November 5, 1947, that their office does not have a listing of such clinical facilities, and when such inquiries are received, they are referred to the respective state health department. We followed exactly the same procedure with the American Cancer Society, requesting them to furnish us with a list. They too are in the process of preparing a list of doctors who are qualified to stain and diagnose the Papanicolaou smears. They would not, however, evaluate the qualifications of the doctors. To our way of thinking, a listing of this type would add very little, and as a matter of fact might detract from the original purpose for which it was prepared, since doctors who would take the smears would be inclined to send them to the persons listed without any knowledge of the qualifications of the individual who would make the diagnosis.

At the last meeting of the American Society of Clinical Pathologists, the writer had occasion to discuss the problem with many of the men, including those who discussed the problem at the conference on cytology smears. At that meeting the Papanicolaou technic was given a "thorough run-down" without the benefit of any proponent for the technic being present. The writer discussed the nontechnical aspects of such a "going over" and suggested that an organization such as the American Society of Clinical Pathologists should be in a position to have a more qualified appraisal of the technic and, furthermore, to recommend from among their members those who were qualified and those who were not qualified to diagnose by the technic.

As far as we know, the American Medical Association has not attempted to standardize or evaluate the qualifications of any of the men in the technic.

The foregoing should prove that we have not taken on the sale and distribution of the apparatus indiscriminately. We have on our part done whatever possible to keep the application of the technic in ethical qualified hands which should, we believe, be the responsibility of the medical profession in general and the various specialized medical societies in particular.

Mention is also made of the fact that we offered, together with the materials for the Papanicolaou test, a hundred slides of various types of cells found in cervical smears. This collection of slides is our "Medichrome" series MG3. They were made with the cooperation of Dr. J. Ernest Ayre of the Royal Victoria Hospital in Montreal. Dr. Ayre is one of the most active proponents of Dr. Papanicolaou's technic.

The "Medichrome" collection of 2 by 2 inch (35 mm.) kodachrome photomicrographs and photographs is, we feel, a very definite contribution to the field of medical education. The collections cover many branches of the medical specialties. Each series has been developed with one or more well known authority in the field. The names of the men connected with this project will verify this statement. We therefore feel that the reference to "a hundred slides of various types of cells found in cervical smears" is unwarranted.

From the foregoing, we belive it will also be agreed that the statement "the offer implies that special training is not necessary to secure and to examine the specimen" is not implied at all.

We should like it clearly understood that the Clay-Adams Company, Inc., while a commercial organization in business for profit, would not under any circumstances sacrifice its well established ethical methods for any monetary gain. Our activities in the medical field substantiate this statement. However, the company is made up of human beings, and human beings are not infallible. We are always open to suggestion, particularly suggestions which are constructive, and we are open minded to the extent that we would gladly modify any of our advertising or promotional activities to conform to what the doctors and medical profession in general expect of us.

Emil Davidson, vice president,
Clay-Adams Company, Inc.,
New York 10.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Cancer Ascribed to Stilbestrol—Statute of Limitations.—The plaintiff sued for damages resulting from the alleged malpractice of the defendant physician. From a judgment of the trial court dismissing the complaint, the plaintiff appealed to the district court of appeal, second district, division 3, California.

The plaintiff alleged that she engaged the defendant physician in January 1942 to examine her physical condition and prescribe medical treatment therefor From that time to June 1943, the defendant prescribed a substantial quantity of medicine containing stilbestrol in tablet form and on June 1 directed the plaintiff to obtain a hundred more tablets to be taken at the rate of one daily. After she had taken these tablets, she took twenty-six more on the directions of another physician, whom she is also suing. The plaintiff further alleged that stilbestrol is a synthetic estrogen containing cancerous properties which may produce or cause cancer of a woman's breast, particularly of a woman with a family history of cancer of the breast, and should not be administered for prolonged periods of time. When its administration is indicated, it should be prescribed only after a physical examination of the patient has been made. According to the plaintiff, the defendant physician knew that the plaintiff had such a family history in that her mother had had cancer of the breast and had died therefrom. On or about Jan. 15, 1945, while the plaintiff was under the care and treatment of the defendant and another physician, there developed in her right breast a lump, which laboratory tests on Feb. 8, 1945 disclosed to be cancer. On Feb. 10, 1945, she was required to and did submit to the removal by surgery of her right breast in order to prevent the cancer from growing and spreading to other parts of her body. In conclusion the plaintiff alleged that she did not know that the drug so prescribed for and taken by her contained properties which might cause her to sustain cancer of the breast and that the cancer developed because of the failure of the defendant physician to possess or exercise that degree of skill and learning ordinarily possessed and exercised by other skilful physicians practicing in Los Angeles County in the prescribing of such medicine over such a long period of time.

"It is the settled law in this state," said the court, "that an action by a patient against a physician and surgeon for injuries sustained by the former, by reason of the negligent or unskilled treatment of the latter, is an action sounding in tort and not upon a contract. Such an action is therefore barred by the provisions of subdivision 3 of section 340 of the Code of Civil Procedure one year after the date of the injury." The defendant contended that the action had not been filed within one year.

The date of the injury, which starts the running of the statute of limitations, said the court, is not necessarily the same date as that when the negligent act or omission of the physician took place. The defendant conceded the applicability of this rule to cases arising from surgery, in which the patient subsequently discovers foreign substances such as sponges, clamps, tubes, pieces of broken bones and other objects to have been left in his body, but contended that it does not appy to the administration or introduction into the patient's body of a drug or medicine. We fail to find any basis of differentiation, however, in the respective situations, said the court. The nature or character of the foreign substance or matter introduced into the body of the patient by the physician is immaterial. The physician is chargeable with knowledge and foresight, to the degree of learning and skill possessed by physicians of good standing practicing in the same locality, of both the nature and effect of such foreign substance or matter on the patient. Where injury proximately results from the negligent act of the physician on whom the patient has relied for information as to his physical condition as well as for the results that may reasonably be anticipated from the introduction into his body of the foreign substance or matter, including drugs and medicines, the statute of limitations does not commence to run until the patient knows, or in the exercise of ordinary care should have known, the cause of his injury.

The plaintiff's amended complaint alleges facts showing that the plaintiff first discovered the bodily injury, accruing to her as a proximate result of the alleged negligent act of defendants, on Feb. 8, 1945. Her complaint was filed within the one year period following such discovery, and therefore the defense of the statute of limitations was unavailable to the defendant. Accordingly the judgment of dismissal in favor of the defendant in the trial court was reversed.—*Agnew v. Larson, 185 P. (2d) 851 (Calif., 1947).*

Medical Motion Pictures

FILM REVIEW

Hypothyroidism—Physiology, Diagnosis and Treatment. 16 mm., color, sound, 1,600 feet (one reel), showing time forty minutes. Prepared in 1946 by J. Lerman, M.D., the Massachusetts General Hospital, Boston. Produced by the Medical Film Guild, New York under a grant from the Maltine Co., New York. Procurable on rental from the Medical Film Guild, 167 West Fifty-seventh Street, New York 19.

The film is an illustrated lecture covering the early knowledge of the thyroid; the histology of the thyroid gland; the classification of hypothyroidism with a discussion of each of the classes, that is, cretinism, juvenile myxedema, adult myxedema and pituitary myxedema; the regulation of thyroid activity; the etiology of hypothyroidism; the physiologic actions of the thyroid hormone in detail; the pharmacology of the thyroid secretion with a few notes on the use of radioactive iodine and the Geiger counter; the biochemistry of thyroid globulin and technic of extraction; the methods of assay of thyroid preparations; the technic of determining the basal metabolic rate; the diagnosis of hypothyroidism; its treatment, and the use of thyroid in other conditions. It is regrettable that the author tried to include so much in one film. The pictures, still and moving, of patients with various types of hypothyroidism are good. These plus a discussion of the diagnosis of hypothyroidism are sufficient in themselves to make an excellent motion picture. The discussion and diagrams illustrating the relationship of the thyroid gland to the other endocrine glands are clear and to the point. The charts contain much information, but they flick by too fast to leave much of an impression. A few illustrations are meaningless and could well be eliminated. If, after the sprint through the biochemistry of the thyroid hormone, the pace was slowed and the treatment of hypothyroidism was revealed more leisurely, there would be enough material for another informative lecture. As it is, the listener has little time to absorb the facts and as a result retains little of the information.

The suggestion for additional uses of thyroid medication in conditions other than hypothyroidism need further amplification to avoid misleading implications; for instance, the use of thyroid for obesity with or without a low basal metabolic rate should be reserved for persons who have hypothyroidism, and many warnings (including some from the Council on Pharmacy and Chemistry) have been issued to this effect. Nor can this be generally regarded as a useful substance for amenorrhea and habitual abortion except in the presence of hypothyroidism. There are a number of inaccuracies in the film, for example, it is not correct to say that the use of globulin fraction of the thyroid is the preferred treatment. It may be preferred by those concerned in producing the film but certainly is not true for other firms nor would it be supported by all clinicians. The trade product "proloid" (a thyroglobulin preparation from thyroid gland, containing 2 per cent iodine in organic combination) is mentioned, but the picture gives no information on its exact dosage or its advantages and disadvantages as compared with other thyroid preparations. A frank description of the product accompanied by open discussion of its advantages and disadvantages, if any, would have served better.

If a reasonably well informed physician were to view this film a dozen times he would undoubtedly obtain a thorough knowledge of hypothyroidism. To the physician who is well versed in diseases of the thyroid most of the film is rather boring. It is difficult to visualize a suitable audience for it. In an effort to cover the entire field in so short a time and to make an all-inclusive appeal to all groups, the specific educational value to any particular group has been destroyed.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, Feb. 28, page 644.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1948. Sec., Dr. D. G Gill, 519 Dexter Ave., Montgomery 4

Arkansas: * *Examination.* Little Rock, June 3-4 Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock

California: *Oral.* San Francisco, June 5-6; Los Angeles, Aug. 7-8. *Written Examination.* Los Angeles, Aug. 9-12. *Oral and Clinical Examination for Foreign Graduates.* San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

Colorado: * *Examination.* Denver, June 21-23. Final date for filing application is June 5. *Endorsement.* Denver, April 6. Final date for filing application is March 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

Connecticut: * *Examination.* March 9 10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic Examination.* Derby, March 9-10 Sec., Dr. J. H Evans, 1488 Chapel St., New Haven.

Delaware: *Examination.* Dover, July 13. *Endorsement.* Dover, July 22. Sec., Dr. J. S. McDaniel, 225 S. State St., Dover.

District of Columbia: * *Reciprocity.* Washington, D. C., March 8. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 E Municipal Bldg., Washington.

Florida: * *Examination.* Jacksonville, June 29-30. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami Beach 41.

Idaho: Boise, July 13-15. Sec., Bureau of Occupational Licenses, Miss Estella S. Muliner, 355 State House, Boise.

Illinois: Chicago, April 6-8. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Springfield.

Indiana: *Examination.* Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

Iowa: * *Examination.* Iowa City, March 15-17. Comm., Dr. Walter L. Bierring, Dept. of Health, Des Moines.

Kansas: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J F. Hassig, 905 N. 7th St., Kansas City.

Kentucky: *Examination.* Louisville, June 16-18. Sec., Dr. P. E. Blackerby, 620 S. 3d St., Louisville.

Maine: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland

Maryland: *Medical Examination.* Baltimore, June 15-18. Sec.-Treas., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, June 15-16. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Massachusetts: *Examination.* Boston, March 9-12. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston.

Mississippi: Jackson, June 1948. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

Missouri: *Examination.* St. Louis, May 24-26. Final date for filing application is April 24. Exec. Sec., Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

Montana: Helena, April 5-7. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

Nebraska: * *Examination.* Omaha, April 5-7. Dir., Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln 9.

Nevada: Carson City, May 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Hampshire: *Examination.* Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, June 15-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

North Carolina: *Endorsement.* Pinehurst, May 4. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

Ohio: *Endorsement.* Columbus, April 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma: * Oklahoma City, June 2-3. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: * *Endorsement.* Portland, May 7-8. Final date for filing application is April 23. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia & Pittsburgh, July. Act. Sec., Bureau of Professional Licensing, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Rhode Island: * *Examination.* Providence, April 1-2. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Written Examination.* Columbia, June 21-23. *Endorsement.* April 5. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee: * *Examination.* Memphis, March 24-25. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Utah: *Examination.* Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: *Examination.* Richmond, June 18-19. *Endorsement.* Richmond, June 17. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., Roanoke.

West Virginia: Charleston, April 5-7. Comm., Public Health Council, Dr. N. H. Dyer, State Capitol Bldg., Charleston.

Wisconsin: * Milwaukee, June 29-July 1. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

Wyoming: *Examination.* Cheyenne, June 7. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, March 16. Sec., Mr. Francis A. Roy, Science Hall, Univ. of Arizona, Tucson.

Arkansas: Little Rock, May 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

District of Columbia: *Examination.* Washington, April 19-20. Sec., Dr G. C Ruhland, 4130 Municipal Bldg., Washington

Florida. *Examination.* June 5. Final date for filing application is May 23 Sec., Mr M. W Emmel, Univ of Florida, Gainesville

Iowa: Des Moines, April 13, July 13, Oct 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids

Michigan: *Examination.* Ann Arbor and Detroit, May 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

Minnesota: *Examination.* Minneapolis, April 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, May 4-5. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, March 21. Sec., Miss Marguerite Kilkenny, 114 E. Marcy, Santa Fe.

Oklahoma: Oklahoma City, April 2. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, June 19. Sec., Basic Science Examining Committee, Mr. C. D Byrne, Univ of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, June 4-5. Sec., Dr. G. M. Evans, 310 E. 15th St., Yankton.

Tennessee: Memphis, March 15-16. Sec., Dr. O. W. Hyman, Univ. of Tennessee, 874 Union Ave., Memphis.

Wisconsin: *Examination.* Madison, April 3. Sec., Dr. W. H. Barber, Scott & Watson Sts., Ripon.

Council on Medical Education and Hospitals

PLAN FOR UNIFORM INTERN PLACEMENT

The following new agreement for internship placement was unanimously approved by the Association of American Medical Colleges at its meeting at Sun Valley, Idaho, on Oct. 28, 1947. Subsequently the plan has been endorsed by the Council on Medical Education and Hospitals of the American Medical Association, the Council on Professional Practice of the American Hospital Association, the Catholic Hospital Association and the Protestant Hospital Association.

Plan for the Year 1948-1949 for Internships Beginning July 1, 1949

1. Applications and credentials to be submitted only through the dean's office to hospitals, with the date for filing applications and release of credentials by the medical schools set at Oct. 15, 1948. Credentials ordinarily will consist of an executed application blank and a letter from the dean but do not preclude such letters from members of the faculty as they may wish to write, unsolicited by the candidate.

2. Applicants may visit hospitals and be interviewed by hospital intern committees, but the hospital administration shall not commit the hospital or obligate the applicant, or potential applicants, before Nov. 15, 1948.

3. No intern appointments shall be made prior to Nov. 15, 1948 from applicants who are members of the senior class in medical school. Hospitals may decline an applicant at any time.

4. Applicants shall accept or reject hospital appointments before midnight of Nov. 18, 1948.

5. These regulations shall apply only to undergraduate medical students who have not completed the fourth year of their medical school course.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage *(6 cents if one and 18 cents if three periodicals are requested)*. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

An Analysis of Time Relationships Within Cardiac Cycle in Electrocardiograms of Normal Men: V. Effect of Changing Heart Rate upon Q-T Interval and T-P Interval and Their Respective Relationships to Cycle Length (R-R Interval). I. Schlamowitz.—p. 878.

Myocarditis Associated with Nasopharyngitis and Tonsillitis.—Gore and Saphir encountered in the material of the Army Institute of Pathology 35 instances of nonrheumatic myocarditis associated with infections of the upper respiratory tract. Acute tonsillitis was present in 12, and acute nasopharyngitis in 23. The diagnosis of pharyngeal or tonsillar infection was made clinically. Streptococci were cultured from the throat in 12 and from the heart's blood, post mortem, in 3. Septicemia was not considered of etiologic moment since visceral alterations were absent in all 35, and negative blood cultures were obtained in 13. Although the pathologic studies indicated that all patients died of cardiac failure, heart disease was suspected clinically in only 3, and in 15 patients death was unexpected. Significant clinical observations which would seem to be of importance in the recognition of the process were: disproportion of the temperature and pulse rate, hypotension, thready or feeble pulse and substernal oppression. Cyanosis, dyspnea and orthopnea occurred frequently. Necropsy findings included significant enlargement of the heart in many cases. The microscopic changes, similar in both nasopharyngeal and tonsillar infections, have been classified. There appears to be significant correlation between the clinical occurrence of hypotension and the severity of the myocarditis, since it was a feature in every case of severe disease in which the blood pressure was recorded. The only available electrocardiograms (four), abnormal in every case, were from patients whose hearts showed muscle degeneration. Anginal pains were related to the presence of hypotension. Attention is called to the danger involved in the intravenous administration of fluids.

Etiology of Clubbing of Fingers.—Mauer says that although toxic, neuritic, mechanical, static, anoxic and other factors have been considered in the etiology of clubbing of the fingers, no theory has gained wide acceptance. Clubbing of the fingers and toes, and the more severe "pulmonary" osteoarthropathies and periostitides, occur when there is arterial anoxia due to congenital or acquired lesions or residence at high altitude. It occurs in many disorders in which the erythrocyte sedimentation rate is rapid, but arterial oxygen saturation normal. In all these cases the vascular bed is wide, blood flow rapid and the tissue warmer than normal. It had been suggested that rapid sedimentation rates, with intravascular formation of rouleaux, interfered with oxygenation of the tissues by decreasing the diffusion surface per unit of hemoglobin. Mauer suggests that with escape of rouleaux through the arteriovenous anastomoses so numerous in the fingers and toes, rapid blood flow and high levels of arterial and venous oxygen saturation may be present simultaneously with low oxygen tension in the digital tissues. Thus, rapid rates of blood flow and low oxygen tension in the tissues would provide the same mechanism for clubbing in chronic infections, neoplasms or metabolic defects leading to abnormal levels of fibrinogen and globulin, as in the classic cases of arterial anoxia. The most rapidly evolving and the most severe types of osteoarthropathy are seen in cases of mediastinal and pulmonary tumors in which the sedimentation rates are rapid and arterial anoxia is present. In rheumatoid arthritis, in Raynaud's disease and in Buerger's disease clubbing is rare, although tissue anoxia is severe in the latter two and rapid sedimentation rates are characteristic of the former. But in all of these, flow of blood and temperatures of the tissues are low in the tips of the extremities. It is concluded that for the development of clubbing low oxygen tensions must occur in tissues which are warm and in which the blood flow is greater than normal.

Inhibition of Ventricular Tachycardia by Atropine.—In the course of studies on the effects of sympatholytic agents Wilburne and his co-workers observed that the rapid intravenous injection of epinephrine provides a simple and effective method for the experimental production of ventricular tachycardia in the intact, unanesthetized animal. Atropine sulfate, 1.3 mg. administered intravenously, prevented the development of ventricular tachycardia. Apparently this is due, in some cases, to the action of atropine in permitting the sinus node to discharge at a rate more rapid than that of the ventricular focus, the former thereby retaining its pacemaker function. Not all cases can be explained in this way. It appears that atropine operates also on the acetylcholine esterase system to prevent reflex cholinergic actions of epinephrine. Atropine seems to be of value in preventing ventricular tachycardia and maintaining a sinus tachycardia. This is of particular importance in myocardial infarction, in which the evolution of recent ventricular tachycardia to fibrillation may be averted. It is suggested that the beneficial effects of atropine in lowering mortality in experimental ligation of a coronary artery may be due in large part to its prevention of ventricular tachycardia and terminal ventricular fibrillation.

*Cell Cleaning Therapy and Liver Cell Gymnastics in Treatment of Chronic Hepatitis. B. O. C. Pribram.—p. 365.

Ileo-Colic Fistula Due to Cancer of Descending Colon: Operative Results. A. Strelinger.—p. 371.

Liver Cell Gymnastics in Hepatitis.—Pribram points out that when a dye is injected in preparation for cholecystography, it disappears from the blood within thirty to forty minutes. The gallbladder becomes visible by roentgen ray as a rule only about fourteen hours following the injection. When, after the dye, 20 cc. of a 50 per cent solution of dextrose is injected, the gallbladder gives a shadow of sufficient density within two hours. When a large amount of dextrose is suddenly offered to the liver cell, it cleans out the stores of other products to make space for the increase in its glycogen. While with an ample supply of dextrose one is in a position to favor and to reinforce the assimilatory function, one is able through the application of thyroxin, to stimulate the dissimilatory phases. This training might lead to increased functional activity of a damaged liver cell. The liver cell gymnastics employed by the author were *started* by injection of a hypertonic solution of dextrose (20 cc. of a 50 per cent solution) intravenously. Then, two days of dextrose-insulin treatment were followed by two days of thyroxin injections with complete omission of carbohydrate from the diet. These rhythmic gymnastics were continued for six weeks. This method of treatment has been tried on patients with chronic hepatic insufficiency, in many types of hepatitis and especially in cases of cirrhosis. In the latter cases particularly, the results could be called convincing and sometimes even dramatic. Since the outbreak of the war brought the follow-up work to an end, the author is unable to say how long improvement lasts and whether the liver cell gymnastics can bring the process of liver destruction to a standstill. He believes that this scheme of treatment is worth trying, as it involves no risks.

Streptomycin in Early Pulmonary Tuberculosis.—Jenkins and his co-workers treated 23 patients with recently acquired pulmonary tuberculosis by intramuscular administration of 2 Gm. of streptomycin daily in divided doses every four hours for ninety days while on a specially supervised program of bed rest. An additional 22 patients received the same schedule of bed rest but without the drug. The majority of patients in this study had serious tuberculosis at the onset of treatment. On the basis of evidence provided by roentgenographic observations and bacteriologic data, it appears that streptomycin exerts a beneficial effect on the course of early pulmonary tuberculosis in excess of what may be obtained by bed rest as the sole form of treatment. These observations do not extend beyond a period of six months after the initiation of the treatment. The earlier in the course of the disease streptomycin therapy is started, the better and more consistent are the results. Streptomycin, in their experience, has exerted a somewhat more beneficial effect thus far on hematogenous or nonconfluent types of pulmonary infiltrations than on dense, confluent lesions.

Excretion of Streptomycin into Tuberculous Cavities.—Steenken and his co-workers report sixty streptomycin assays on the material recovered from large tuberculous cavities, the tracheobronchial tree and the pleural space of 13 patients who received streptomycin intramuscularly in doses of 1.8 to 2 Gm. daily. The individual dose was usually 0.3 Gm. every four hours. The average concentrations of the drug in the tuberculous cavities, the pleural space and the tracheobronchial tree were much greater than those which completely inhibit the growth of tubercle bacilli in vitro.

Streptomycin in Tuberculous Tracheobronchitis.—Brewer and Bogen treated 44 patients with persistent, severe, ulcerating and granulating tuberculous lesions of the trachea and larger bronchi with streptomycin. Thirteen patients were given combined intramuscular and aerosol inhalation treatment with large dosage of a total of 2.4 to 3 Gm. daily. All patients showed rapid, complete healing. Less rapid and less uniform results were obtained in 12 patients who received smaller doses intramuscularly (2 Gm. daily) and in 12 patients treated by aerosol alone. Vestibular paralysis developed in all the patients receiving 2 Gm. of the drug daily for over two months and in some of those receiving 1 Gm., but most of them learned to compensate fairly well. Other toxemic phenomena included anorexia, nausea, vomiting, vertigo, tinnitus, stomatitis and eosinophilia. Such rapid and complete healing as with the combined intramuscular and aerosol inhalation treatment has not been observed in other patients with similar lesions observed previously or simultaneously under different therapeutic regimens. This study indicates that streptomycin is the most effective therapeutic agent in the treatment of the most severe types of active tuberculous tracheobronchitis, but further work is needed regarding dosage and route of administration.

Histoplasmosis.—Miller and his co-workers report a case of histoplasmosis in a man aged 37, a farm laborer, in whom an ulcer of the tongue developed. The diagnosis was established five months before his death by isolation of Histoplasma capsulatum in cultures of biopsy from the walls of the ulcer. There was histoplasmosis of the cervical and axillary lymph nodes with a possible terminal invasion of the blood stream by the parasite. Treatment with sulfadiazine, stibamine glucoside ("neostam," a pentavalent organic antimony preparation), penicillin and roentgen rays was of no value. There is no satisfactory treatment for a disseminated infection with H. capsulatum. The patient had coexistent Hodgkin's disease as indicated by the clinical course and by the discovery at necropsy of a malignant lymphoma, best classified as so-called Hodgkin's sarcoma, and disseminated miliary tuberculosis which probably caused his death. Biopsy of skin or of lymph nodes is the most successful method of diagnosis of histoplasmosis during life. Examination of blood smears, bone marrow and splenic pulp may be of value, but in all instances the diagnosis must be confirmed by isolation of the fungus in culture. In the authors' patient the histoplasmin, coccidioidin and haplosporangin tests gave equivocal results. The reaction to Napier's serum test was negative and to Wolff's precipitation test positive. A study of 88 cases of histoplasmosis reported in the literature reveals that cutaneous or mucomembranous lesions were present in 45 (about 50 per cent). H. capsulatum was observed in a large percentage of these cutaneous lesions, as it was in the authors' case. The sources of infection, the mode of transmission and the portals of entry of H. capsulatum are not known. More evidence is required before it can be definitely established that an infection with H. capsulatum ultimately leads to pulmonary calcification or that sensitivity to histoplasmin is associated with calcification in those with a negative reaction to tuberculosis.

Sensitivity to Sulfonamide Ointments.—Gottschalk and Weiss gave patch tests to a group of 223 volunteers with a 5 per cent sulfadiazine ointment (p_H of base, 7 to 7.5). Two hundred and ten volunteers had patch tests with a 5 per cent sulfathiazole ointment (p_H of base, 7 to 7.5). Two hundred volunteers had patch tests with a 5 per cent sulfadiazine ointment (p_H of base, 8.1). Of these volunteers 2.3 per cent were sensitized to the first sulfadiazine ointment, 0.49 per cent were sensitized to the sulfathiazole ointment, and none were sensitized to the second sulfadiazine ointment. In the patch test the material is applied only once, in only a small amount and to one area of the skin. The authors feel that epithelial sensitization may take place with greater facility when under actual conditions the sulfonamide drugs are used on previously inflamed skin and over larger areas of surface. They also believe that when the sulfonamide drugs are used on the skin for more than five days the probability of sensitization is greatly increased.

Varicelliform Eruption.—Ruchman and his co-workers report 4 cases of Kaposi's varicelliform eruption in 3 adults and in a 14 month old boy, all of whom had preexisting atopic dermatitis. The fact that 3 of the patients were adults appears of importance, as the disease is apparently much less common in adults than in children. One of the adult patients had a clinical relapse of the disease thirty-nine days after the first attack, and between these attacks, on the twenty-second day after the first episode, she had labial herpes. Each of the 4 patients had been in contact from five to ten days preceding the onset of Kaposi's varicelliform eruption with 1 or more persons who had labial herpes. The 3 adults had been successfully vaccinated at an earlier date. None of the 4 patients had any known exposure to vaccine virus preceding the development of Kaposi's varicelliform eruption. Penicillin, plasma and immune globulin failed to influence the course of the disease. A filtrable agent recovered from the cutaneous lesions of each of these 4 patients was shown by histologic methods and appropriate cross immunity tests in animals to be a strain of herpes simplex virus. An increase in antibodies during convalescence was demonstrated in 2 patients. In 1 fatal case in an adult there were no antibodies in the acute stage. These 4 cases add corroborative evidence to that already accumulated that Kaposi's varicelliform eruption may be produced by infection with herpes virus in persons having atopic dermatitis. The recovery of the herpes virus distinguishes this from eczema vaccinatum which is due to infection with the vaccine virus in persons having atopic dermatitis.

Ascorbic Acid in Poison Oak Dermatitis.—Klasson treated 126 patients having poison oak dermatitis with ascorbic acid. The average period of treatment was five days, the shortest two days and the longest ten days. The earlier treatment was initiated after exposure, the quicker and more favorable was the recovery. The ascorbic acid was given only to those patients who presented manifestations of moderately severe or severe disease. The dosage varied somewhat and depended on the severity of the dermatitis; it is felt that the maximum daily dose in any case is 600 mg. of ascorbic acid. The dose was divided into two or three portions given at intervals of four to six hours. The best route of injection seems to be the intramuscular one. When ascorbic acid is given orally, twice the amount that is employed by injection should be given. When vesiculation is present topical application of calamine lotion is recommended as a supportive measure. The first sign of improvement is a reduction in itching. This may come about two to four hours after the first injection but wears off in a few hours if no further ascorbic acid is given. In no instance were any inflammatory reactions noted. The best results are usually obtained in persons with symptoms of edema, as of the eyelids and genitals. It is felt that ascorbic acid is capable of combating the disease. Twenty-four men sensitive to the plant were employed as subjects in tests to determine prophylaxis against poison oak dermatitis. Through its physiologic action ascorbic acid has possibilities in preventing the contraction of poison oak dermatitis with daily doses from 150 to 300 mg. taken in tablet form in divided doses, one day prior to exposure, every day during exposure and at least twenty-four to forty-eight hours after exposure.

Anesthesia for Bronchoscopy and Laryngoscopy.—Lorhan and Roberts point out that some observers have advised against the use of curare in bronchoscopy. They used the combination of "intocostrin" (a curare preparation) and "pentothal sodium" for laryngoscopy and bronchoscopy in 27 cases and feel that this combination has much to offer. In using "intocostrin" and "pentothal sodium" in combination, a minimal amount of each is required to produce the condition necessary for successful endoscopy. The authors obtained good relaxation in all but 1 of their 27 patients. Respiratory depression was encountered in 2 of the patients, the use of neostigmine becoming necessary in 1 of them, after which the patient's respiration improved. The procedure described should not be attempted unless the anesthesiologist is prepared to combat respiratory depression and institute artificial respiration immediately by means of a gas machine. One cubic centimeter of a 1:2,000 solution of neostigmine methylsulfate should be prepared and given if thought necessary. Oxygen should be given continuously to maintain a high oxygen concentration.

Artificial Kidney.—Murray and co-workers point out that the principal aspects of the artificial kidney are: (1) a dialyzing membrane which is selective in allowing the passage from the blood stream of some substances and not of others, namely, nonprotein nitrogen and other toxic substances, (2) a method of circulating the blood through this extrinsic system and (3) protection from removal of necessary substances from the blood stream. After extensive trials and experiments the authors finally arrived at the present setup, which works satisfactorily both experimentally and in clinical patients. The authors describe the evolution of the machine, its use in animals and a clinical case in which cure followed the use of the artificial kidney. The membrane can be used to remove toxic substances from the blood. With proper buffering of the dialysate, there should be no injurious effects as a result of this process.

Blalock Operation for Tetralogy of Fallot.—Dodrill defines the Blalock operation as the anastomosis of one of the systemic arteries from the aortic arch to either the right or the left pulmonary artery. This may be done by either an end to side or an end to end method of suture. The operation is indicated in cases of congenital pulmonary stenosis or atresia of the pulmonary orifice. The diagnosis of pulmonary stenosis is made on the presence of cyanosis, clubbing of the fingers and toes, increased red blood cell count and the appearance of the heart in roentgenologic and fluoroscopic examination. The author reviews observations made in thirteen operations on 12 patients. In 5 patients the common carotid artery was used for the anastomosis, and in the remaining patients the subclavian artery. Results were excellent in 5 cases; the cyanosis disappeared, the red blood cell count became decidedly decreased, the clubbing of the fingers and toes receded or disappeared and the physical reserve of the patient was greatly improved. The arterial oxygen saturation has increased in all patients who survived the operation. Three of the patients died, usually soon after the operation. In those who survived there have been few complications. One patient, a boy aged 4½ years, deserves special mention, because he showed evidence of mental deficiency. He could not talk and acted as though he had no cerebrum. After the operation the nurses noticed that the child took interest in things about him. He pointed to the food he desired and he began to play with toys. He is now in a kindergarten school, but although there was decided improvement following the operation, the mental status is now apparently not progressively improving. Since the preparation of this paper, 11 additional patients have been operated on, with 1 fatality. This death was due, at least in part, to acute laryngotracheobronchitis.

Vitamin Metabolism After Burns.—Lund and his associates studied alterations in the plasma concentration of ascorbic acid and the urinary excretion of ascorbic acid, thiamine, riboflavin and N-methylnicotinamide in patients with burns admitted to the Boston City Hospital during 1944-1945. There were 4 children with minor burns and 2 children with severe burns, 11 adults with minor burns and 4 with extensive burns. After severe burns there were considerable alterations in the metabolism of ascorbic acid, thiamine, riboflavin and nicotinamide, as evidenced by a low concentration of ascorbic acid in the plasma either with the patient fasting or after saturation tests and low urinary excretion of these vitamins either with the patient fasting or after the injection of test doses. The extent of the abnormalities paralleled the severity of the burn. The changes were greatest in the early period following injury but continued in some cases far into the chronic stage. In this respect, the upset in vitamin metabolism parallels the upset in nitrogen metabolism which follows burns. The authors think that large doses of ascorbic acid, thiamine, riboflavin and nicotinamide are needed by severely burned patients and that some supplementation at a lower level is needed for many patients with burns of moderate extent. It is suggested that 1 to 2 Gm. of ascorbic acid, 10 to 20 mg. each of thiamine and riboflavin and 150 to 250 mg. of nicotinic acid be given daily to severely burned patients and that the doses may be needed for long periods. These vitamins alone will not satisfy the nutritional needs of the patient, which include a high protein, high carbohydrate diet and ample quantities of yeast, crude liver extract (given orally) and vitamins A and D.

Chemotherapy of Urinary Infections.—Hewitt stresses that necessary prerequisites for successful chemotherapy of infections of the urinary tract are a free flow of urine without obstruction, drainage of localized accumulations of exudate, absence of foreign bodies within the urinary tract or wounds with granulating surfaces communicating with the urinary tract, and renal function sufficient to secrete the chemotherapeutic agent in bactericidal concentrations in the urine. Mandelic acid has been largely supplanted by newer, more potent drugs. Sulfathiazole and sulfadiazine are effective against almost all the common bacterial pathogens isolated from the urinary tract. The use of sulfonamide mixtures is a possible method for reduction of renal complications. Penicillin is the most potent agent for the eradication of gram-positive cocci in the urinary tract, as well as for the treatment of metastatic suppurative complications arising in the urinary tract during infections with these bacteria. In the presence of mixed infection with gram-negative bacilli, combined treatment with sulfonamide compounds or streptomycin is indicated. Streptomycin is effective against most of the gram-negative bacilli. Resistent cultures of Pseudomonas aeruginosa and Streptococcus faecalis are an indication for increased dosage. Alkalinization of the urine is an important adjunct to streptomycin therapy.

Hypertonic Saline Infusions in Differential Diagnosis of Diabetes Insipidus.—Carter and Robbins present evidence to the effect that alterations of urine flow of hydrated subjects, following infusion of hypertonic saline solution, permit a differentiation between diabetes insipidus and psychogenic polydipsia and polyuria. Normal subjects and patients with polyuria and polydipsia were studied. All antidiuretic therapy was stopped for a period sufficient to permit the reappearance of polyuria and polydipsia. Fluids were withheld for eight hours preceding the test. The subjects were hydrated with water, 20 cc. per kilogram by mouth, over a period of one hour. Thirty minutes after the period of hydration was begun, an indwelling catheter was inserted. Specimens of urine were collected in fifteen minute periods and flow of urine was calculated in cubic centimeters per minute. After two control periods with an adequate flow of urine, i. e., greater than 5 cc. per minute, an infusion of 2.5 per cent sodium chloride was begun. The hypertonic saline solution was administered intravenously at the rate of 0.25 cc. per kilogram per minute for forty-five minutes. If no decrease in flow of urine occurred during the infusion or in the first two postinfusion periods (fifteen minutes each), 0.1 unit of "pitressin" N.N.R. was given intravenously and its effect on flow of urine observed. Nine healthy young adults showed a prompt decrease in flow of urine during the infusion or the first period thereafter. Two patients with moderate renal insufficiency showed a prompt reduction in flow of urine comparable to the normal subjects. Of 11 patients with polyuria and polydipsia without glycosuria 8 showed a continued diuresis during and after the infusion with a prompt reduction of flow of urine following the administration of "pitressin." These results provided objective support for the clinical impression that these patients had diabetes insipidus due to insufficiency of the neurohypophysis. Three of the subjects with polyuria and polydipsia showed the decrease in flow of urine characteristic of the normal subject. The psychogenic origin of their polydipsia and polyuria was confirmed by their subsequent freedom from symptoms without replacement therapy.

Hemoglobin Solutions for Intravenous Infusion.—Hamilton and his associates point out that for infusion purposes hemoglobin solutions have advantages over whole blood in that the former do not need to be typed and cross matched and that longer preservation is possible. The authors describe work that was undertaken to provide a method whereby large volumes of hemoglobin solution could be prepared in a sterile state, free from stroma material, of electrolyte content approximating that of plasma and capable of preservation without change of the active hemoglobin to methemoglobin. It was found that large volumes of solution can be rapidly prepared, with 95 to 98 per cent of the hemoglobin in the active form capable of combining with oxygen. Solutions stored at 4 C. showed no conversion of hemoglobin to methemoglobin over a period of two and one-half months; over a six month period a small and variable amount of methemoglobin may be formed.

Direct Infiltration of Radioactive Isotopes.—Hahn and his associates say that in attempts to radiate the lymphoid macrophage system, manganese dioxide sols were found to be gradually liberated, with evidence of secretion by way of the biliary tract. In the case of the gold sols, however, the radioactive material remained in the tissues in which it had been deposited (that is, chiefly the liver and the spleen) for as long as measurements could be made. It was determined whether the insolubility of gold colloids in body fluids could be used to advantage in direct infiltration of neoplastic tissue. Ordinarily the gold sols for intravenous administration were made up to contain 2 Vanderbilt units (V U.) per cubic centimeter. Such concentrations of radioactivity were usually found to be too low for infiltration work, because of the necessity of injecting relatively large volumes of solutions. Therefore the gold colloids were concentrated by boiling so that 5 or more units per cubic centimeter were obtained. The "Vanderbilt unit" represents about two thirds of a millicurie. A single "Radiation Unit" consisting of 16 mg. of gold foil, which has been exposed to a flux of slow neutrons, would have on an average about 120 V.U. at time of removal from the uranium pile. It has been found that approximately 40 V U. of Au^{198} administered by vein to an adult of average size may result in a remission in chronic lymphocytic leukemia. In cases of discrete encapsulated lesions, the colloid was administered in the same manner as would be employed for infiltration of a solution of procaine. After infiltration, frequent measurements were made. After describing observations on several clinical cases, the authors say that direct infiltration of insoluble radioactive colloidal sols of gold is apparently a suitable manner in which to deliver radiation to a discrete mass of tissue. Most of the subjects treated represented far advanced cases in which trial of materials whose correct dosage was unknown was felt justified. Usually the patient was grossly undertreated. In 1 patient with carcinoma of the vagina the tumor mass was such as not to hold injected fluid, and practically all of the radioactive colloid leaked out. Another approach to such problems would be the instillation of $Ag^{111}NO_3$, in which the caustic action offers hope of tying the agent to the tissue. The feasibility of use of $AgNO_3$ has been tested in experimental animals by using $Ag^{105,110}$ made by neutron capture in $AgNO_3$. The half-life is two hundred and twenty-five days and therefore not suitable for human studies.

Aneurysms of Coronary Arteries in Infant.—Pickard and his associates present the case of a girl who had been well till the age of 1 year, at which time, because of rash and fever, which was believed to represent erythema multiforme, she was hospitalized. The patient was discharged as improved on the seventeenth hospital day. Three months later she was readmitted because of dyspnea, orthopnea, anorexia and fatigue on slight exertion. The infant died several hours after admission. Necropsy revealed that the left coronary artery had a normal ostium but the lumen was narrowed to pinpoint size at the bifurcation. The anterior descending branch of the left coronary artery presented a fusiform enlargement. It measured 10 mm. in its greatest diameter. An adherent thrombus measuring 30 mm. and completely occluding the lumen was found in this branch of the left coronary artery. A portion of the thrombus occluded the circumflex branch at its origin. There were evidences of recent and remote infarction in the anterior portion of the interventricular septum and the anterior and apical portions of the left ventricle. Microscopically vascular changes representing healing and healed polyarteritis nodosa were observed.

Oral Penicillin in Infants.—Husson gave penicillin, 20,000 units contained in 5 to 10 cc. of water and put in a formula bottle, to 22 infants between the ages of 1 week and 5 months and ranging in weight from 6 to 12 pounds (2,722 to 5,443 Gm.). The administration of the drug was followed by a regular feeding. Serum levels were determined one-half, one, three, four and six hours after ingestion of the penicillin. At one-half hour the average of six measurements was 0.880 unit per cubic centimeter. At one hour the average of twenty-two measurements was 0.584 unit per cubic centimeter. At two hours the average of ten measurements was 0.360 unit per cubic centimeter. At three hours the average of twenty-two measurements was 0.265 unit per cubic centimeter. At four hours the average of five measurements was 0.045 unit per cubic centimeter. At six hours no penicillin was found in the serum of the 5 infants tested. All the levels up to and including three hours after ingestion were therapeutically adequate. Gastric acidity, which according to other workers is an obstacle to the absorption of ingested penicillin, never reaches adult levels in children until the third year. This factor may account in part for the high penicillin levels obtained in almost all of the author's determinations. The relative inefficiency of the infant kidney may be another factor of considerable importance in the production of the high sustained serum concentrations of orally administered penicillin. A third factor is the possibility that there are fewer penicillinase-producing organisms in the infant gastrointestinal tract. Oral administration of penicillin would therefore seem to be a safe and practical method of treating infections in infants caused by the ordinarily penicillin-sensitive organism.

Oral Penicillin and Rheumatic Fever. — Maliner and Amsterdam report observations on 44 children between the ages of 1 to 13 years, with infection of the upper respiratory tract. Twenty-two children, 12 boys and 10 girls, received lozenges of 1,000 to 5,000 Oxford units of penicillin. The patients were advised to suck the troche slowly about one hour after each meal. Twenty-two children, 11 boys and 11 girls, were observed as controls without penicillin. None of the children receiving the penicillin prophylaxis showed signs of rheumatic activity, whereas 4 of 22 control patients presented definite attacks of rheumatic fever. The authors feel that their results are encouraging and warrant further detailed study which may definitely help to establish penicillin as the agent of choice in rheumatic fever prophylaxis.

Cerebral Abscess Complicating Fallot's Tetralogy.—Hand reports the occurrence of a large abscess in the left temporosphenoidal region, of a second abscess in the occipital lobe on the same side and of a similar focus of infection in the parietal lobe, associated with pulmonary stenosis, defect of the ventricular septum and hypertrophy of both ventricles in a boy 5½ years old who died two days after trephining of the left temporal region. Reports of 36 cases of congenital heart disease with abscess of the brain in the literature, when compared with the rather infrequent occurrence of congenital cardiac lesions in the average run of medical practice, justify the belief that these patients as a class have greater susceptibility to this complication than all the other medical groups of children, even those with otitis or with acquired cardiac lesions. This susceptibility should receive greater attention in textbooks and in courses in pediatrics, internal medicine, neurology and surgery. All patients in whom pulmonary stenosis, defect of the ventricular septum, coarction of the aorta or patent ductus arteriosus is definitely proved or even suspected should be examined by a surgeon especially trained in surgery of closure of a patent ductus or of anastomosis of the pulmonary artery with the aorta. The improvement in oxygenation following the operation of anastomosis undoubtedly favors improvement in general health even if it may not lessen the possibility of paradoxic embolism. The operation for occlusion of the patent ductus arteriosus might lessen the tendency to have acute endarteritis or endocarditis which these patients are likely to show even in adult life, but it will certainly remove the possibility of cerebral abscess by paradoxic embolism. It would therefore seem to be strongly indicated in these patients with patent ductus unless there is some equally strong contraindication.

Cavernostomy.—O'Brien and his associates report on 43 patients with low cardiorespiratory reserve (group 1) with reduced function of the other lung which precluded collapse therapy or pulmonary resection. After cavernostomy, the disease in 13 is apparently arrested or improved; in 3 it is unimproved; in 5 the operation was too recent for classification; 20 are dead. Thirteen patients (group 2) had a residual cavity beneath a thoracoplasty collapse. In 6 of these the disease is apparently arrested, and in 1 it is improved; 1 was operated on too recently for classification and 3 are dead. Two others in this group had an incomplete operation and are unimproved. A large cavity of the lower lobe not closed by pneumothorax or phrenic paralysis or both was present in 8 patients (group 3). Five have arrested disease and 1 is unimproved. Drainage of the cavity was attempted but not achieved in 2 others; in 1 the disease is now apparently arrested and 1 is dead. Cavernostomy was done on 10 patients (group 4) with active or progressive tuberculosis and miscellaneous indications for surgical intervention. Five of these had previous unsuccessful Monaldi intercostal drainage which was converted to cavernostomy. Two patients are improved; 2 are unimproved, and

6 are dead. Most of the postoperative complications and deaths occurred in patients who before operation had visible dyspnea at rest, or active, progressive tuberculosis. Nearly 75 per cent of the deaths were attributable to these two factors.

Removal of Foreign Bodies from Heart.—Harken says that more than one half of the patients referred to the thoracic center at the 160th General Hospital, United States Army, in the European Theater of Operations as having foreign bodies "in the heart" were found not to have these missiles in the heart when careful fluoroscopic examination was done. Approximately one third of the missiles considered to be intracardiac were not found in the heart at surgical exploration. These two factors indicate that a foreign body cannot be conclusively diagnosed as intracardiac without surgical exploration or autopsy. Three operations are described in detail. The first was performed for the removal of a foreign body from an abscess in the pericardium and two operations were done for the removal of foreign bodies in chambers of the heart. These operations were taken from a series of operations in which one hundred and thirty-four missiles were removed from the mediastinum. Of these foreign bodies, fifty-five were pericardial and thirteen were in the chambers of the heart. Seventeen cardiotomies were performed. There were no deaths. Harken thinks that certain foreign bodies should be removed from the heart: (1) to prevent embolus of the foreign body or associated thrombus, (2) to reduce the danger of bacterial endocarditis, (3) to avoid recurrent pericardial effusions and (4) to reduce damage to the myocardium. Also pain and cardiac neurosis may be factors influencing the decision to remove some cardiac missiles.

Latent Rheumatic Myocarditis.—Rogers and Robbins state that rheumatic fever, a systemic disease affecting chiefly the heart, has always been considered to be primarily a disorder of childhood. The fact that initial as well as recurrent acute attacks of rheumatic carditis occur in the later years of life is not so well known. The authors studied all cases of acute rheumatic myocarditis coming to necropsy at the Mallory Institute of Pathology of the Boston City Hospital from 1933 to 1946. In 20 of 41 pathologically proved cases of active rheumatic myocarditis the usual clinical manifestations of activity were sufficiently striking to result in a clinically correct diagnosis. Most of these patients were in the first two decades of life. The remaining 21 cases were not diagnosed as active rheumatic disease during the terminal illness; the most characteristic feature of this group was the age, which except in 5 cases was over 40 years. In 10 of these 21 patients a previous diagnosis of rheumatic heart disease had been made, and the terminal cardiac decompensation was considered to have been on a mechanical valvular basis without the complicating presence of myocarditis. In 7 more of the clinically undiagnosed cases no diagnosis of rheumatic disease had been made in the past, nor was it entertained during the terminal illness. In all but 1 case rheumatic manifestations were absent from this group, and the disease took a truly silent form. The 4 remaining patients represented subclinical acute rheumatic myocarditis occurring without associated pericardial or endocardial involvement. In these cases the diagnosis could hardly have been suspected clinically. The difficulty of clinical recognition of rheumatic activity in older patients can be attributed to several factors: in these age groups active carditis often assumes an atypical form; active rheumatic myocarditis as a cause of cardiac failure may be obscured by the presence of complicating diseases, such as hypertension, arteriosclerosis and healed rheumatic valvular disease, and in a certain number of cases the disease may be entirely silent.

Thoracolumbar Sympathectomy in Hypertension.—Lord and Hinton discuss principles of management during the operative and postoperative period that evolved as the result of their experience with 400 patients subjected to the two stage thoracolumbar sympathectomy during the past five years. The maintenance of a relatively stable pressure has been best achieved during the operation by the use of 2 cc. of a "solution neosynephrine hydrochloride, 1 per cent" in 1.000 cc. of 5 per cent dextrose in distilled water administered intravenously and, postoperatively, by the same fluid with 1 cc. of the drug per 1,000 cc. of solution until the systolic blood pressure has been stabilized at 90 or 100 or higher. This may take only a few hours or as long as forty-eight hours. The second major problem in these patients is to obtain hemostasis and to deal with the open thorax during the operation as well as to prevent serious hemothorax, pneumothorax, atelectasis and pneumonia postoperatively. The authors make use of the closed anesthetic system. Anesthetic agents included ether, cyclopropane and ethylene. When hemostasis has been obtained after the removal of the sympathetic chain and suture of the diaphragm, the wall of the chest is closed around a large rubber catheter placed in the pleural space. Air is completely aspirated, the catheter removed and the skin closed without drainage. Oxygen therapy is used in patients with low preoperative cardiac reserve. Digitalization of patients preoperatively is effected when evidence of actual or impending congestive heart failure is present, and the drug is continued after operation. Penicillin in liberal doses is given intramuscularly when the operation has been more difficult than usual or when the pleura has been widely torn, with potential trauma to the lung by retraction. Early ambulation is practiced only after the first stage sympathectomy. After the second operation patients are allowed up when the blood pressure has been stabilized and when the cerebral and cardiac functions are adequate. In a few patients who preoperatively had had either a stroke or a coronary occlusion, the authors have cautiously used subcutaneous heparin in Pitkin menstruum postoperatively.

Late Effects of Total Gastrectomy.—MacDonald and his associates studied intestinal motor function, intestinal absorption, pancreatic function and the blood picture in 3 patients who have survived total gastrectomy for three, five and ten years, respectively. All patients have a normal desire for food and become hungry. All are on an unrestricted, mixed diet, but take care that the food is well cut and well chewed. Occasionally, they experience borborygmi and mild cramps of the upper part of the abdomen after eating. The weight, although it increased after the operation, has never regained the levels existing before illness. Although it has been postulated that the secretion of pancreatic enzymes is greatly reduced after removal of the stomach, studies on pancreatic enzymes in these cases, however, yielded essentially normal figures except in case 2, in which total gastrectomy, splenectomy and partial pancreatectomy had been performed. This patient experienced difficulty in maintaining weight. Dilatation of the jejunum was present. Pancreatic enzymes were deficient, and the vitamin A tolerance curve flat. The glucose tolerance curve showed hyperglycemia, which was sustained. In the other patients, the vitamin A tolerance curves showed an apparently delayed but otherwise normal absorption of the vitamin. Glucose tolerance tests disclosed early and pronounced but transient hyperglycemia. Blood studies demonstrated that in 2 of the 3 patients a macrocytic, hyperchromic anemia developed two and five years respectively after operation. The other had received prophylactic treatment with liver. A review of the literature revealed a high incidence of macrocytic, hyperchromic anemia in patients surviving total gastrectomy for three or more years.

Fatal Renal Disease in Carbon Tetrachloride Poisoning.—Stobbe reports a case of carbon tetrachloride poisoning in a crane operator, in whom renal manifestations dominated the clinical picture. Two days before admission the patient had emptied two fire extinguishers containing carbon tetrachloride to stop a fire in the cab of the crane, and had stayed in the cab all day. The patient died on the twentieth hospital day. He was a diagnostic problem because on admission he seemed to have only acute glomerulonephritis. A few days later, the history of exposure to carbon tetrachloride, associated with oliguria, low specific gravity, hematuria, albuminuria and hypertension justified a diagnosis of nephrosis. It is postulated that the acute onset of headache, nausea and vomiting followed by the aforementioned syndrome was due to the production of phosgene gas Heart failure developed because of potassium intoxication resulting from renal damage. With intraperitoneal lavage the potassium level and the electrocardiogram returned to normal. The intraperitoneal lavage was discontinued because of fever, dyspnea and abdominal distention after Escherichia coli was cultured from the lavage fluid, suggesting peritonitis. Penicillin, streptomycin and sulfadiazine were given. Sulfonamide intoxication as shown by the high level of sulfadiazine in the blood and cutaneous eruptions was largely contributory to the final acidosis. Necropsy disclosed central necrosis and fatty metamorphosis of the liver, profound acute nephrosis with primarily epithelial lesions and slight peritonitis like that which might be caused by hypertonic solution of sodium chloride. The recovery of E. coli in culture was probably due to contamination.

"Mesantoin" in Epilepsy.—Fetterman and his co-workers treated 50 patients with epilepsy with 3-methyl-5,5-phenylethylhydantoin ("mesantoin"). Most of the adult patients received four to six tablets (0.4 to 0.6 Gm.) daily, but in some instances seven and eight tablets (0.7 to 0.8 Gm.) were given. Twelve patients obtained a remarkable reduction in the frequency of seizures and 17 were considerably improved; 8 have shown but slight to moderate improvement; in 10 patients the drug has not achieved any significant change in the condition thus far, and 3 patients are listed as total failures. "Mesantoin" has been relatively free of toxic side reactions. Many of the patients complained of drowsiness, but dextro-amphetamine sulfate proved useful in counteracting this lethargic effect. "Mesantoin," like diphenylhydantoin, is valuable for grand mal and jacksonian attacks and not for petit mal. It has proved more effective than phenobarbital alone and compares rather favorably with diphenylhydantoin sodium. Even if its anticonvulsant properties may be less than those of diphenylhydantoin, its side actions are milder and larger doses can be safely tolerated. Though "mesantoin" is effective alone, its major role in the authors' experience has been as a supplement to diphenylhydantoin sodium. The combined use of 0.3 Gm. diphenylhydantoin sodium and 0.2 Gm. to 0.6 Gm. of "mesantoin" daily gives the patient the sum of their anticonvulsant properties, while each neutralizes the side actions of the other, making this combination especially valuable in the control of grand mal seizures.

*Roentgenographic Appearance of Persistent Pulmonary Infiltrates Associated with Sensitivity to Histoplasmin. M. L. Furcolow, H. L. Mantz and I. Lewis.—p. 1711.

Pulmonary Infiltrates and Sensitivity to Histoplasmin.—Furcolow and his associates point out that pulmonary calcifications, which were long assumed to be the end product of healed tuberculosis, are demonstrated roentgenologically rather frequently in persons with a negative tuberculin reaction. Although the view was advanced that this phenomenon represented simply the reversion to negative of a once positive tuberculin reaction, the demonstration of a strikingly uneven geographic distribution of these cases suggested that some disease other than tuberculosis was responsible. An indication that histoplasmin might be the responsible organism was furnished by Palmer, Christie and Peterson. Furcolow and his co-workers describe the roentgenologic characteristics of persistent pulmonary infiltrations found among persons who are sensitive to histoplasmin but not to tuberculin. Among 72 asymptomatic cases in school children in Kansas City, Mo., only a few of the lesions were limited to the lymph nodes, a few were of the disseminated type and approximately two thirds were nodular, sharply circumscribed foci. The remaining one fourth were diffuse patchy infiltrations with poorly defined borders, which sometimes developed into nodular lesions. Similar lesions were seen in a few patients whose symptoms appeared to arise from this infection. In some of the lesions a central core of calcification was noted. The lesions calcify slowly, and many infiltrations persisted without complete calcification during the two years of observation. The authors conclude that in regions where histoplasmin sensitivity is widespread pulmonary infiltrations as well as calcifications are frequently nontuberculous, and can be differentiated from tuberculosis at present only by cutaneous tests.

Gastrointestinal Tract in Regulating White Corpuscles.—Experiments by Boccuzzi and Paolino in 9 patients with pernicious anemia revealed that in the great majority of them, after a plain protein meal and after a meal of highly cooked liver, the digestive leukocytosis (with the exception of the leukopenic phase) was missing, while it was clearly evident if the meals still had in them the so-called antipernicious principles. Additional experimental research and clinical observations supported the concept of the participation of the gastrointestinal tract and above all of the stomach in regulating the hematic leukocytic picture as follows: There are constant and characteristic alterations of the white series in pernicious anemia *not secondary* to those of the red series; there is also stimulating action of the leukopoiesis by the gastric and liver extracts, not only in patients suffering from pernicious anemia but also in other leukopenias and in normal subjects. The digestive leukocytosis, often missing in processes which profoundly alter the gastric mucosa and digestive leukocytosis, may be reproduced in these cases by adding extracts of gastric mucosa to protein meals or by the ingestion of liver. In patients with carcinoma of the stomach leukocytosis is often missing and is substituted by leukopenia, which may be pronounced, particularly in cases of tumors involving the mucosa of the pyloric antrum. Leukopenia with relative lymphocytosis may be observed frequently in patients with various diseases, all of them associated with anatomic and functional alterations of the gastrointestinal tract, such as simple gastric achylia, essential hypochromic anemia, gastric resections and typhoid.

Acute Coronary Occlusions.—Doles treated 58 patients, 40 men and 18 women between the ages of 39 and 78 years with acute coronary occlusion, with vitamin K. The acute coronary occlusions in these patients were all associated with hypoprothrombinemia of various degrees; it was the basis for the rationale of this treatment. The amount of vitamin K usually given is from 50 to 72 mg. every six to eight hours by the intramuscular and intravenous routes until the prothrombin reaches 100 per cent of normal. The number of inadequately treated patients who died was 3. Two of the 55 adequately treated patients died; this gives a mortality rate among the latter of 3.6 per cent. In 53 patients the pain of acute coronary occlusion was controlled within twenty-four hours and a normal recovery followed. Fifty-two have been able to pursue their original occupations. Not any of these patients complain of pain or show any evidence of decompensation. The blood pressures have maintained the same level as before the attack. The prothrombin times average 98 per cent of normal. The fact that pain remained absent as long as the prothrombin was above 70 per cent of normal and that it was controlled after the administration of vitamin K emphasizes the concept of the relation of pain to hemorrhage within the wall of the coronary artery. Pain recurred when there was a return of hypoprothrombinemia. It is suggested that if routine prothrombin determinations are carried out on all patients, the detection of an early hypoprothrombinemia and the prompt use of vitamin K should be factors in reducing the incidence of acute coronary occlusion.

Autoagglutinins in Hemolytic Anemias.—Renner and McShane report the occurrence of hemolytic anemia in a white woman aged 71 in whom the autoagglutinins were demonstrated to be active at body temperature. Necropsy was performed and sections of the spleen showed masses of closely packed red blood cells undergoing destruction. Some of the blood vessels contained antemortem thrombi. These findings suggest that intravascular agglutination and destruction of red blood cells occurred in this patient. There are in the literature 8 additional cases of acquired hemolytic anemia associated with autoagglutinins active at body temperature. The association of autoagglutination, hemolytic anemia and multiple phlebothromboses in 18 cases of atypical pneumonia in the literature strongly suggests that intravascular agglutination does occur in vivo and is responsible for both the anemia and the thromboses. In the authors' concept autoagglutinins play a causative role in the pathogenesis of certain hemolytic anemias. The action of the autoagglutinins in destroying red blood cells is undoubtedly complemented by other factors: increased mechanical fragility of the clumped cells as suggested by Damashek, erythrostasis in the spleen and other portions of the reticuloendothelial system as suggested by Ham and Castle and the action of lysins elaborated in the body as suggested by Bergenhem and Fahraeus.

Periodic Paralysis in Exophthalmic Goiter.—According to Seed periodic paralysis occurs most commonly as a familial inherited trait but also occurs sporadically. The sporadic cases are found almost entirely in males and have a tendency to be associated with exophthalmic goiter. The disease is characterized by repeated attacks of flaccid paralysis commonly appearing after prolonged periods of rest, most frequently on waking in the morning. The author cites a man, aged 23, whose family history indicated a tendency toward goiter. About two months after he had been in a shipwreck, which, however, had not impaired his health, his shipmates observed that he was becoming "pop-eyed." About a month later he felt the first signs of weakness of the muscles. A few days later he had the first attack of complete paralysis; these spells continued to occur daily in various degrees for about three weeks. He was admitted to the Hines Hospital on April 9, 1946, and remained there until August 9. During this period his symptoms had lessened in severity. He believed that improvement began when he was given daily therapeutic doses of a vitamin B complex. He was placed on iodine medication and the basal metabolic rate dropped to plus 5 and zero and minus 6. From July 30 to August 9 he received 100 mg. of thiouracil daily. Improvement continued and he was discharged on August 9, free of symptoms. Medication was discontinued. In a few weeks he noticed some recurrence of symptoms and on October 2, awoke to find himself unable to use his arms, legs or trunk. In addition to his muscular weakness, he had the symptoms of a thyrotoxicosis. On October 24, he was placed on 25 mg. of propylthiouracil three times daily. His muscular weakness gradually became less severe. He had occasional spells of morning "numbness" but had no difficulty for the next three months while under continuous propylthiouracil medication. Long continued therapy may or may not produce a permanent cure.

Streptomycin in Tuberculous Meningitis.—Debré and his associates describe the investigation which is being carried out by a team of pediatricians, ophthalmologists, neurosurgeons, pathologists, bacteriologists and chemists at the Hôpital des Enfants Malades in Paris. Their preliminary conclusions are based on 70 cases. In the early stage of their investigation the authors stressed the following points: (1) employment of large doses of streptomycin, 100,000 to 200,000 units per kilogram of body weight per day; (2) administration of the drug by both the intraspinal and the systemic route, and (3) prolonged treatment. The treatment which they are now using comprises a phase of attack and of maintenance. The phase of attack consists of large doses: 100,000 units of the drug per kilogram per day by the parenteral route and at the same time two intraspinal injections per day of 50,000 to 100,000 units. This treatment is continued for about a week. In the second phase treatment is maintained at doses below 50,000 units per kilogram per day by means of parenteral injections alone. The authors attach the greatest importance to examinations of the fundus oculi and the cerebrospinal fluid. At present 46 children who have been undergoing treatment for from two to ten months are behaving like normal beings. The problem of when to stop the treatment is most difficult. Forewarned by early errors of the gravity of premature cessation of treatment, which was followed by fatal relapses, the authors have not yet dared to make the decision. They are treating the children continuously, as diabetic persons are treated with insulin. They have now decided not to discontinue treatment until they have the support of a large number of reassuring signs: absence of all clinical meningeal symptoms, an ascending weight curve, complete apyrexia, normal sedimentation rate and a spinal lymphocyte count below 10 at repeated examinations. They would add to this absence of tubercle bacilli in culture and, if possible, a normal quantity of cerebrospinal albumin.

Second Attack of Poliomyelitis.—Second attacks of poliomyelitis are not common. Alves and Pugh report that a girl, who had the first attack when she was 3½ years of age had a second when she was 12. The following factors were observed in both attacks: a fairly typical history in the presence of an epidemic; muscular paralysis and weakness, and changes in the cerebrospinal fluid, namely, increased cell count and raised protein content.

Tetralogy of Fallot.—Murray lists as the characteristic features of the syndrome of Fallot (1) stenosis of the pulmonary artery, (2) patent interventricular septum, (3) dextra position of the aorta and (4) hypertrophy of the right ventricle. There are many variations from these particular features. Most children with this condition die at birth or soon after. A few live to 6 or 7 years of age, even to 10 or 12. Occasionally one will survive to adult life. The patient suitable for surgical intervention is the child who has survived for perhaps a year or more and has limited exercise tolerance. The principle of the surgical treatment developed chiefly by Blalock and Taussig is to take a large branch from the aorta and anastomose it with the pulmonary artery so that more blood passes through the pulmonary circulation. The patient turns from blue to a satisfactory pink color. Since the operation is of considerable magnitude a mortality rate of 17 per cent as given by Blalock and Taussig is not surprising. Murray says that in his series of 60 cases of congenital heart disease with operation 40 were Fallot's tetralogy; 11 patent ductus arteriosus and 9 other types. The over-all mortality was 11.7 per cent and in the tetralogies 7.5 per cent.

Adrenal Hemorrhage in Monocytic Leukemia.—Lauckner and Hebbert report an abscess in the axilla and signs of anemia in a school girl, aged 11. The patient's condition was recognized as monocytic leukemia. The first transfusion of blood was followed by improvement, but in the course of the second transfusion circulatory failure quickly developed and the patient died. Necropsy revealed bilateral adrenal hemorrhage apparently precipitated by blood transfusion. The histologic features are described, and attention is drawn to the giant cells in the tissues. The nature of these cells is discussed. There is a paucity of reports of adrenal hemorrhage in leukemia, although this might be expected to occur not infrequently. Hemorrhagic reactions to blood transfusion are briefly reviewed.

Accidental Electrocution.—In the case reported by Dickson the area of immediate contact and point of entrance of the 240 volt alternating current was the right temporal pole of the brain, through a trephine opening in front of and slightly above the right ear. This opening had been made for a minor operation of the trigeminal nerve, and an electrically lit retractor had just been inserted when there was a sudden short circuit, the exact nature of which was not ascertained. There appeared to be no fault in the diathermy apparatus, and it was thought that the resistance in the transformer might have been momentarily defective. A nurse standing between the electric apparatus and the patient also received a shock, and, having her hand on the patient, presumably acted as the conductor of the current from patient to earth. The patient immediately became unconscious and remained so until next day, when both respiration and cardiac action stopped and she died twenty-one and one-fourth hours from the time of the accident. The most noteworthy change in the brain was a widespread disruptive process in both gray and white matter, believed to have been produced by the action of the electric current in liberating bubbles of steam and gas as a result of the intense heat and electrolytic action.

Inclusion Bodies in Organs of Infants.—In the examination of the organs of 2 infants dead from hemolytic disease of the newborn Cappell and McFarlane observed in many tissues giant cells with cytoplasmic and intranuclear inclusion bodies. The affected cells conform to those previously described as protozoon-like, and the lesions are identical morphologically with those attributed to the action of the salivary gland virus of rodents and other animals. By analogy with the experimental transmission of the salivary gland virus in animals, it is suggested that the widespread lesions of infants are probably due to dissemination of a human strain of salivary gland virus. Isoimmunization of the mothers by any of the known blood group antigens carried by the fetus has been excluded in both cases.

Personality Change After Leukotomy.—Frankl and Mayer-Gross studied patients who were discharged to their homes after having been subjected to leukotomy. Of 170 patients operated on 77 were discharged, but 9 of these had to be readmitted after being home from two to twenty months. Fifty-one of the patients had had long standing schizophrenia of the catatonic and paranoid types; 9 were obsessional neurosis, 7 melancholia and 1 recurrent mania. Eight patients could be interviewed, the others had to be followed-up by letter. More than half of the 68 patients (a fifth of the total), who without the operation would have been hopeless chronic invalids, earn their living, and more than three-quarters are usefully employed. The patient's working capacity and attitude toward work, interests and hobbies, social, family and sex life are described. The patient is physically healthy, a good eater and sleeper, with considerable euphoria. His prevailing mood is cheerfulness; he does not worry but is happy and contented. He has a high opinion of himself. He may take his responsibilities too easily or may shirk them altogether. He is restless and likes movement and change. His interests and hobbies are varied and variable, with a preference for light entertainment and superficial pastimes. His relations with the persons near him are often without depth of feeling. He shows little sympathy or consideration for his next of kin or anybody else. He neither regrets nor repents for whatever he may have done or said. He may be self willed, headstrong and unable to see the other person's point of view. He tends to quickly passing outbursts of temper. He may attend to his work as before or may do less well, but he invariably thinks he does well. Symptoms of the former psychosis, delusions, hallucinations, obsessional ideas and rituals seemed to be insignificant.

Viability of Treponema Pallidum.—During the war Lumsden received capillary tube samples from venereal sores from isolated units, after they had been in transit for four or five days. The question often arose as to the reliability of this procedure. He decided to investigate the viability of T. pallidum in preparations made from fresh untreated lesions. In 10 consecutive cases of typical hunterian chancre of the penis in which he had just found T. pallidum on dark field examination, he made several preparations which were examined subsequently at intervals. In cases in which the tubes were stored in an incubator at 37 C. (98.6 F.), T. pallidum remained viable at least six days (in 1 case ten days). When the tubes were stored at a room temperature of 5 to 18 C. (41 to 64.4 F.) the organisms remained viable ten and thirteen days. In one instance, in which the tube was not properly sealed, spirochetes could not be identified on the tenth day. In 8 additional instances the original slide preparations in which T. pallidum had been identified were sealed with soft paraffin and stored either at room temperature or in an incubator at 37 C. In each case T. pallidum was viable for eight to fourteen days. The author thinks that it is perhaps not sufficiently appreciated that T. pallidum is fairly viable outside the human body. In human necropsy material kept in the refrigerator the spirochetes have been found motile after forty-eight hours. Enormous numbers of T. pallidum may be present in, for instance, macerated fetuses, suggesting that T. pallidum can multiply in dead tissue under anaerobic conditions. Accidental infections, though rare, undoubtedly can and do take place in the necropsy room and in the laboratory.

Methylthiouracil in Hyperthyroidism.—Frisk says that at his hospital treatment with derivatives of thiouracil has been employed for over three years. He analyzes results in 126 of 145 patients who have been continuously treated with methylthiouracil or allied compounds for more than two months. Forty-four per cent of the patients were free from symptoms within one month and 72 per cent within two months. The rest of the patients showed a slow response. Of previously untreated patients, those with palpable enlargement of the thyroid reacted most satisfactorily. Iodine therapy immediately prior to treatment with methylthiouracil delays the therapeutic result. Toxic adenomas responded slowly to this treatment. It was possible to maintain the patients in a state of remission by small daily doses of the drug. Enlargement of the thyroid gland is common during prolonged treatment. There is often a hypercholesterinemia. In one fifth of the patients the elevation in the serum cholesterol level was considerable and persisted for one to thirteen months. Eleven patients were submitted to thyroidectomy. In 7 instances treatment was discontinued for various reasons. With a treatment time of less than six months the recurrence frequency was about 50 per cent; with a time of over six months the frequency was around 10 per cent. Toxic reactions were observed in 11.6 per cent of patients. Leukopenia with a white blood cell count of less than 3,000 developed in 7 patients; in 4 it appeared during thiouracil therapy and in 3 during treatment with methylthiouracil. One of these patients had agranulocytosis. All of them recovered.

Formaldehyde-Treated Poliomyelitis Virus Vaccines.—Gard and Lindholm present a preliminary report on partially purified inactivated poliomyelitis virus as an immunizing agent. The purpose of the experiments was to produce in mice a serologic immunity sufficient to afford reasonable protection against invasion of the virus from the periphery. Subcutaneous injection of partially purified and inactivated virus of poliomyelitis gives rise in mice to increased resistance against subsequent intraperitoneal infection with active virus. Protection against more than 10,000 lethal doses can be obtained. Formaldehyde in excess causes loss of the immunizing capacity of the vaccine. The safety range of concentration of formaldehyde between complete inactivation of the virus and partial destruction of the antigenicity is extremely narrow. The variation as to the minimum concentration necessary for inactivation is considerable and is dependent on the amount of formaldehyde-fixing impurities present in the virus preparations. For large scale production of vaccine a standard procedure and standard purity tests must be applied. Such methods have still to be elaborated.

Thyroid Symptoms in Diabetes Mellitus.—Schulze and Franke observed among 223 patients who were under treatment and supervision on account of diabetes mellitus, 28 or 12.5 per cent who had more or less pronounced signs of involvement of the thyroid. In 6 patients hyperthyroidism was primary and the diabetes secondary, whereas in 22 the diabetes mellitus preceded the onset of the thyroid symptoms. The frequent occurrence of goiter in diabetes mellitus is the result of an increased thyrotropic action of the anterior lobe of the hypophysis, which in turn is caused by the abolishment of the restraining action of the insulin. The high incidence of ocular symptoms of the exophthalmic type, combined with Graefe's sign, indicates that the hypophysis is the decisive organ. Other symptoms with illustrative case histories discussed by the authors are circulatory symptoms, changes in the metabolic rate, tremor and moist skin. They also stress that in untreated cases of diabetes mellitus a positive reaction to the acetonitrile test (Reid-Hunt's reaction) is frequently apparent, but it becomes noticeably weaker after treatment with insulin. This indicates that insulin normalizes the function of the thyroid in patients with diabetes mellitus.

Determinations of Carbon Monoxide in Blood.—Harders shows that the presence of carbon monoxide can be determined in small quantities of blood with sufficient accuracy by means of the reduction of palladium chloride in the diffusion apparatus of Lips. The precipitated palladium is collected, brought into solution and determined colorimetrically in a concentrated solution of potassium iodide.

Mortality in Diphtheria.—Observations in over 300 cases of diphtheria convinced van Spanje that the promptness with which serum therapy is employed has a decisive influence on the mortality rate. It increases greatly when the administration of serum is delayed. To wait the result of the bacterial examination may involve a threat to the life of the patient. Serum should be administered as soon as diphtheria is suspected.

*Lessons Learned from Campaign of Skin Reaction to Tuberculin in French Army (1934-1947). R. Debénédetti.—p. 801.
Treatment of Diabetic Coma. J. Stahl and D. Kuhlmann.—p. 802.

Skin Reaction to Tuberculin in French Army.— Debénédetti reports on tuberculin cutaneous reaction in 100,000 soldiers of the French army during the period of 1934 to 1946. Approximately 50 per cent of young Frenchmen inducted into the army presented a negative reaction, and a considerable number were still negative in reaction when they concluded their service. The percentage of negative cutaneous reaction was greater among the soldiers who came from rural areas than among those from cities, but there were differences in the percentage of negative reaction among soldiers from various rural areas of France. The conversion of the cutaneous reaction from negative to positive among the soldiers belonging to a certain regiment nearly always occurred in the absence of any clinical manifestation, while the tuberculous morbidity among soldiers with a negative cutaneous reaction surpassed that among soldiers with a positive reaction. Allergy does not develop in the absence of infection, while contamination may occur in the absence of allergy: Koch's bacillus may enter the organism but fail to become fixed or to multiply. It is also possible that a young soldier has become infected and allergic and that he has lost his sensibility to tuberculin, perhaps without losing his immunity. These results show that BCG vaccination of soldiers on a large scale is justified. The unanimous vote of the French Academy of Medicine calls for this type of prophylaxis.

Diagnosis of Silicosis Based on Pulmonary Tissues from Exhumed Bodies. A. Policard.—p. 821.
*Rational Bases of Medical Endobronchial Treatment of Pulmonary Abscess. M. Fourestier and Y. Le Boucher.—p. 822.
Case of Fetal Erythroblastosis Due to Agglutinogen B. R. Heffinck.—p. 823.

Medical Endobronchial Treatment of Pulmonary Abscess.—Fourestier and Le Boucher applied medicinal endobronchial treatment to 10 patients with pulmonary abscess. Immediately after the diagnosis of pulmonary abscess was established the first exploratory bronchoscopy was carried out in order to confirm the exact area of localization and at the same time to remove some of the purulent secretion for bacteriologic examination. Depending on the result of the bacteriologic tests, 400,000 units of penicillin alone (in patients with gram-positive bacteria) or combined with 1 Gm. of a soluble sulfonamide compound (in cases with mixed gram-positive and gram-negative bacteria), was instilled with a catheter by the endobronchial route three times a week for one to two months. This local treatment is essential but must be combined with general treatment for about one month, with a daily dose of 1,000,000 units of penicillin alone by the intramuscular route (in those with gram-positive bacterial growth) or combined with 5 Gm. of a sulfonamide compound given either parenterally or by mouth (in those with gram-negative bacterial growth). Bronchoscopic examination was repeated several times during the treatment. Expectoration often continued even though the endobronchial material no longer revealed any significant bacterial growth. In such cases treatment may be completed with daily injections of 0.5 mg. or more of atropine for ten to fourteen days, to dry up bronchial glandular reflex hypersecretion. All 10 patients made a complete recovery.

*Vitamin K in Therapy of Essential Hypertension. A. Morelli and P. Salvi.—p. 611.

Vitamin K in Therapy of Essential Hypertension.—Morelli and Salvi found that (1) the formation of cholinesterases is increased in the blood serum of patients with essential hypertension and that (2) the intravenous injection of a solution containing 10 mg. of synthetic vitamin K (menadione, 2-methyl-1,4 naphthoquinone) diminishes both hypertension and the formation of cholinesterases in the blood serum of patients. The authors believe that essential hypertension is due to an imbalance of the autonomic nervous system with sympathetic predominance and that vitamin K stimulates the tonus of the autonomic nervous system and reestablishes its balance.

White Blood Cell Picture During Diphtheria.—The observations described by Baumgartner are based on 100 cases of diphtheria which included 21 cases which were toxic and malignant, 30 moderately severe, 31 mild and 18 carriers. He found differences in the leukocytic reaction depending on whether a mixed infection existed (diphtheria bacilli accompanied by streptococci or staphylococci) or whether the diphtheria bacilli were the only pathogenic organisms. The eosinophils and basophils do not disappear in the blood picture of pure diphtheria until the fifth day. Monocytosis exists frequently but lymphocytosis rarely. The mature neutrophils decrease in percentage in accordance with the severity of the toxic manifestations and increase again as the toxicosis subsides. In severe cases the neutrophils always show toxic granulation. The appearance of many immature neutrophils and the decrease in mature neutrophils and a simultaneous increase in leukocytes to over 10,000 is always a dangerous sign, since in such instances there usually developed myocarditis, paralysis and other toxic signs. Two cases of malignant diphtheria with fatal outcome revealed the same picture. Mild forms of diphtheria may manifest a mild leukocytosis, a slight increase in cells with segmented nuclei and a slightly increased deviation to the left, or the blood picture may be normal. Mixed infections exhibit at once the neutrophilic combat phase; eosinophils usually disappear and the lymphocytes decrease, the mature neutrophils predominate and the total leukocyte count increases. Even the mixed infections, however, show the stamp of diphtheric toxicosis. The white blood cell picture is of prognostic value, provided that the type of infection, whether mixed or pure, is taken into consideration.

Prolongation of Action of Penicillin.—Carlinfanti and Morra retard the absorption and prolong the action of penicillin by injecting it subcutaneously and then retarding the venous and lymphatic circulation by the exertion of slight pressure on the part in which the injection is made (thigh or arm) by means of a rubber cuff or band. The pressure must be slightly less than the minimum arterial pressure so as not to make the patient uncomfortable. The constricting band should remain in place for only from one to five hours, depending on the quantity of penicillin injected (10,000 or 100,000 units). This method makes it possible to reduce the number of injections to three a day or to five in forty-eight hours.

Semaine des Hôpitaux de Paris

23:2595-2632 (Nov. 21) 1947

*Treatment of Bronchopulmonary Suppurations with Instillations of Penicillin Controlled by Laryngoscope and Fluorescent Screen. H. Bénard, P. Rambert and C. Coury.—p. 2595.
Attempt of Classification of Primary Intrathoracic Tumors: Incidence—Anatomico-Clinical Peculiarities. M. Bariéty and C. Coury.—p. 2602.
*Folic Acid in Treatment of Anemias. P. Rambert.—p. 2614.

Instillations of Penicillin in Bronchopulmonary Suppurations.—Bénard and his co-workers treated 9 patients with acute or subacute chronic bronchopulmonary abscess by endobronchial instillations of penicillin under pharyngolaryngeal and tracheobronchial local anesthesia with tetracaine hydrochloride. One hundred thousand to 500,000 units of penicillin was instilled in 10 to 20 cc. of isotonic solution of sodium chloride with or without epinephrine and atropine by means of an opaque rubber catheter under control of the fluorescent screen but without bronchoscope. These instillations were first repeated daily, then every two days, and later weekly, or every two weeks. Patients with chronic abscess associated with sclerosis for a duration of twenty months received up to 8,400,000 units of penicillin in forty-two instillations over a period of three months. Complete clinical and anatomic recovery, as demonstrated on roentgenologic examination, resulted in 8 patients; in only 1 patient intolerance of the anesthesia occurred before any endobronchial procedure and prevented the instillation of the penicillin. Complete recovery resulted from this treatment in 36 of an additional 40 cases of bronchopulmonary abscess cited in the literature. This treatment is indicated in cases of recent or chronic abscess of the lung, whether associated with putrefaction or not and in failure of any other route of administration of penicillin. The 90 per cent rate of recovery is considerably higher than that obtained with parenteral administration of penicillin and that with penicillin aerosol therapy. It is not a substitute for surgical treatment but may serve as a useful preoperative treatment in cases in which definite improvement cannot be demonstrated on roentgenologic examination after a course of two to three weeks.

Folic Acid in Treatment of Anemias.—According to Rambert, the satisfactory results obtained by Spies with folic acid in the treatment of macrocytic anemia in the United States have been confirmed in France. This applies exclusively to the hyperchromic anemias associated with medullary megaloblastosis and chiefly to Biermer's disease. A daily dose of 20 mg. of folic acid by mouth has been employed by the author, but 10 mg. seems to be the optimum dose. Increase in appetite and in weight resulted after the first two or three days of treatment, which may be continued for ten to thirteen days. Even high doses up to 400 mg. have been well tolerated. There was a pronounced drop in the iron content of the blood serum and an increase in reticulocytes, red blood cells and white blood cells. Repeated sternal punctures revealed the progressive disappearance of the megaloblasts within a few days. A definite recovery from pernicious anemia cannot be obtained with one course of folic acid treatment. A normal hematologic state resulted from maintenance treatment with folic acid for ten to twenty months in 23 of 25 patients with pernicious anemia. In 1 patient with nutritional macrocytic anemia associated with sprue and with diarrhea of several years' duration, feces were restored to normal on the fourth day of treatment with folic acid. Folic acid by mouth failed in 1 patient with macrocytic anemia in whom calf liver extract was effective. A second course of folic acid treatment failed in another patient who had a remission as a result of the first course of this treatment and in whom calf liver extract remained effective. In spite of the hematologic improvement obtained with folic acid, the drug does not have any effect on the neurologic syndrome associated with pernicious anemia, which is to be considered as a disorder of complex deficiency while folic acid has an exclusive effect on the erythrocytic maturation. Folic acid treatment of pernicious anemia should therefore be combined from time to time with treatment with liver extract.

Semana Médica, Buenos Aires

54:915-944 (Dec. 4) 1947. **Partial Index**

*Particular Exanthem in Psittacosis. A. Averbach and J. Ink.—p. 931.

Exanthem in Psittacosis.—The 1946 epidemic of psittacosis in Buenos Aires, although restricted to certain suburbs in the city, was so highly contagious that frequently 7 of 8 persons living in the same house were ill almost simultaneously. A diagnosis of psittacosis was made because of the fact that the epidemic started from contact of some of the patients with a parrot which died of avian psittacosis, and the clinical symptoms and course of the disease were those of psittacosis. The disease ran a course of atypical pneumonitis, which was benefited by the administration of penicillin. An exanthem not previously described in psittacosis was encountered in all cases in this epidemic. It consisted of an eruption of more or less thick pearl-colored spots, either minute or between 2 and 4 mm. in diameter. The skin at the back of the neck was either normal or slightly red. The exanthem appeared early in the course of the disease and persisted for twenty or forty days. Five cases are reported.

Book Notices

Synopsis of Neuropsychiatry. By Lowell S. Selling, M.D., Ph.D., Dr.P.H., Director, Division of Mental Health, Florida Department of Health, Jacksonville, Florida. Second edition. Fabrikoid. Price, $6.50. Pp. 561, with 27 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This volume, according to its preface, is intended for general practitioners and medical students. For these purposes its size, compactness, brevity and outlined presentation meet the self imposed requirements. However, in the attempt to cover the broad fields of neurology and psychiatry, sketchiness and incompleteness render its reference and study values below par. For example, the student who is continuously plagued by examinations which demand definitions will find that the patient with poliomyelitis may have a stiff neck but will look in vain for "Foerster's sign." He will learn that the ninth cranial nerve supplies the parotid gland, but under the seventh will find no mention of the nerve supply to the submaxillary and sublingual glands. The otherwise excellent differential diagnosis under infantile paralysis makes no mention of Guillain-Barré's polyradiculoneuritis. In the section on treatment of epilepsy there is nothing on the production of acidosis by such agents as racemic-glutamic acid, diets rich in protein and fat, exercise and drugs such as ammonium chloride. The contemporary thought that the reticular formation, through its projected reticulospinal tract, is responsible for extensor posture in man is conspicuous by its absence.

Omissions in the psychiatric portion of the text are more apparent than those in the neurologic section. No mention is made of the associations and psychiatric syndromes usually linked with the endocrines and the vitamins. While morphine, cocaine, diacetylmorphine and marihuana poisoning is described, bromidism is omitted. Nowhere can be found a section devoted to personality and personality testing (Berneuter, Minnesota multiphasic, Rorschach and the like). Of the various schools of psychodynamics, only Freud and Adler, with a dozen lines dismissing Meyer, are mentioned. Constitutionalism, Kempf, Bleuler, Jung and other schools are lacking, although Janet, as the representative of French psychologic thinking, is grudgingly allotted one word over four lines. Under psychotherapy, nothing is said of prefrontal lobotomy, vitamin treatment, the geriatric approach to the mental disorders of old age or such therapeutic adjuvants as dramatics and music.

The illustrations and the diagrams are excellent, as are the various tables. The succinctness and orderly progression of the subjects make the text an easily read one. Physicians may find it quite serviceable as a handy reference, while students will be able to use it as a review for examinations.

Le chirurgien en présence de l'etat diabétique. Par Jacques Bréhant. Préface du Professeur Sénèque. Paper. Price, 1,200 francs. Pp. 543, with 44 illustrations. Masson & C^{ie}, 120 Boulevard Saint-Germain, Paris 6^{e}, 1946.

No comparable book in diabetic surgery has appeared in any other language. The first section covers what the surgeon should know about diabetes, gives general principles of medical treatment, the preparation of a patient with diabetes for surgery, anesthesia and a general discussion of conditions amenable to surgical intervention. In the next part the surgical complications of diabetes are discussed, first from a general point of view and then in detail, taking up infections of the skin, gangrene, ocular complications and miscellaneous surgical conditions. In the third section there is a discussion of surgical types of diabetes such as the infections of the pancreas, the hypophysis, the thyroid and the adrenals together with a discussion of surgery of the biliary tract and in fact the whole gastrointestinal tract in young and old patients. In the fourth section the author discusses those conditions in which surgical intervention in an organ related to diabetes might be undertaken in order to affect the diabetic state. The fifth section relates to diabetes in pregnancy and the sixth, to diabetes in relation to trauma.

The book is carefully conceived and well written, with excellent illustrations. Résumés at the end of each chapter are admirably compiled. Furthermore, there is a delightful quotation from one diabetic author or another at the beginning of the chapters which shows the widespread reading by the author.

With such a beautiful book, there is but one criticism; namely, that the author is not conversant with what has gone on in diabetes during the last four or five years. He is so capable and so well versed in his subject that unhesitatingly one of the larger foundations or a group of surgeons individually or in one of their associations should persuade him to come to this country and spend one or two months in visiting the larger diabetic clinics. His point of view and his criticism of the new work done here for patients with diabetes would be invaluable, and then the second edition of his book would be of such a standard that every surgeon interested in diabetic surgery should possess it.

Common Skin Diseases. By A. C. Roxburgh, M.A., M.D., B.Ch. Eighth edition. Fabrikoid. Price, 21s. Pp. 497, with 220 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W. C. 1, 1947.

The eighth edition of Roxburgh's popular book is, like the previous editions, a clearly written, practical presentation of the subject. It is a personal book reflecting the author's experience in practice rather than a compilation of the abstracts from the literature. The scope is limited to the more commonly encountered diseases of the skin, and emphasis is given to differential diagnosis and treatment, although some of the drugs recommended will be unfamiliar to American readers. It includes a thorough consideration of the antibiotics, particularly penicillin, and it considers also such new developments in dermatology, as the role of DDT for certain parasitic diseases and calciferol for lupus vulgaris. A number of new illustrations have been added, all of which are clear and well selected. The print is large and on good stock. This book warrants the good reception afforded the previous editions.

Ear, Nose and Throat: Symptoms—Diagnosis—Treatment. By George D. *Wolf, M.D., Assistant Clinical Professor of Otolaryngology*, New York Medical College, New York. Fabrikoid. Price, $10. Pp. 523, with 149 illustrations. J. B. Lippincott Co., 227-231 S. Sixth St., Philadelphia 5. 1947.

This work on the ear, nose and throat differs from the usual text in that it approaches its topic from the point of view primarily of symptoms, diagnosis and treatment. As the dust cover states: "Typical complaints by the patient, rather than diseases, are used as topical bases for discussion."

The idea is sound and has been tried previously and with considerable success, especially in Germany. For those for whom it was written, notably students, practitioners, interns and residents, the book offers considerable material in concise form. An idea of what the author has attempted may be gained by reading the first chapter, which concerns itself with ear, nose and throat emergencies. One finds here discussion of the various hemorrhages encountered in this region and of the foreign bodies seen in this area as well as adequate comment on such topics as tracheotomy and cocaine poisoning. In a similar fashion other chapters deal with head pain, vertigo, sore throat, earache, hoarseness and so on.

Although the text concerns itself primarily with symptoms, diagnosis and treatment, it was found necessary to add anatomic details and properly so where these are necessary to clarify understanding.

Knowledge of pathologic facts is also just as necessary for a proper understanding of symptoms, diagnosis and treatment. Here the text seems regrettably brief, a price paid no doubt of necessity by the manner of organization of the text. There are other unbalances which will, it is hoped, be corrected in a future edition, for this work is worthy and plainly fills a need.

A Synopsis of Orthopædic Surgery. By A. David Le Vay, M.S., F.R.C.S. Fabrikoid. Price, 15s. Pp. 242, *with 55 illustrations*. H. K. Lewis & Co., Ltd., 136 Gower St., London, W. C. 1, 1947.

This book is a fair synopsis of orthopedic surgery and covers most of the problems as well as they could be covered in a synopsis. It is intended for senior undergraduates, but there seems to be material missing which would be useful to medical students. In some instances the dissertations are a bit lengthy.

Often there is too much emphasis on some subjects and not enough on others; for instance, too much discussion about ruptured disks with little about the other causes of backache. In general the book could be used as a lecture guide for students if it were integrated with the proper references to other books. It would be more valuable if there were a complete bibliography covering references to all conditions mentioned in the book. It is unfortunate that a book of this type has practically no reference to other than British authors.

The Internal Fixation of Fractures. By Charles Scott Venable, M.D., F.A.C.S., and Walter Goodloe Stuck, M.D., M.S., F.A.C.S. With a foreword by Ralph K. Ghormley, M.D., F.A.C.S., Professor, Orthopedic Surgery, Mayo Foundation, Rochester, Minnesota. Cloth. Price, $5.50. Pp. 237, with 84 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois, 1947.

This comprehensive handbook on the subject of internal fixation consists of chapters presenting a review of the historical data, the investigative work on the use of metals in surgery, evaluations of the various types of metals, the technic of internal fixation as applied to fractures of the upper and lower extremities and, lastly, a recognition of necessary standards and improvements of materials used.

The historical chapter on the early uses of metal appliances and the reasons for the unfortunate results is interesting and instructive, since it lays the foundation for the rather belated investigative and experimental work which led to the recognition in 1934 that interference with healing and the deterioration of the metals used in internal fixation was due to electrolysis, except when infection was a factor. The recognition of this fact led the authors and other investigators to search for metals that were inert in the body tissues.

They emphasized the importance of the surgeon's knowing the type of stainless steel that is to be used, since there are some twenty-five or thirty standard industrial grades that are used, due to the variation in the amount of one alloy or another. The most desirable one at this time is 18-8 SMO stainless steel. They maintain, however, that "vitallium" is the most inert substance in use for internal fixation. Many other metals are discussed and evaluated with respect to their adaptability to internal fixation.

A conservative attitude has been taken toward open reduction. Surgery is advocated only after closed reduction has failed, when internal fixation offers the advantages of accurate approximation and possibly earlier healing and reduction of disability. Technics, indications and pitfalls are concisely discussed. The importance of atraumatic surgical approach is emphasized. The authors believe that internal fixation does not play an important role in damaging the blood supply in fractures of the neck of the femur, whereas inadequate reduction and holding of the reduction is probably more responsible for aseptic necrosis in this type of fracture. They stress the fact that faulty technic and errors in judgment have a direct relation to poor results, also the importance of the necessary armamentarium and skill one must have to perform such surgery.

This book is well illustrated, has an exhaustive bibliography and should form a splendid guide to the fracture surgeon in the use of internal fixation.

An Introduction to Bacteriological Chemistry. By C. G. Anderson, Ph.D., Dip. Bact. Second edition. Cloth. Price, $5. Pp. 500, with 12 illustrations. William Wood & Co., Mount Royal and Guilford Aves., Baltimore 2, 1946.

The first edition of this book appeared in 1938 as a textbook for students and those not primarily interested in the biochemistry of micro-organisms. The approach and method of treatment has not been altered, but the book has been enlarged by about 20 per cent to include sections on chemotherapy and antibiotics, together with miscellaneous new material scattered throughout. The book still fails, however, to include a discussion of disinfection, a curious lack in view of its basic importance to chemotherapy. The treatment of immunity is somewhat more superficial than might be expected and covers little more than the material given the medical student at the present time. Although in no sense sufficiently comprehensive to serve as a reference book, this volume will be of interest to those who desire a summary of the present state of knowledge of the chemistry of bacteria.

A Short Handbook of Practical Anæsthetics. By Höel Parry-Price, M.R.C.S., L.R.C.P., D.A. With a foreword by Cecil P. G. Wakeley, C.B., Consulting Surgeon to the Royal Navy. Cloth. Price, $3. Pp. 127, with 50 illustrations. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; John Wright and Sons, Ltd., Gaunt House, 28 Orchard St., Bristol 1, England, 1946.

This small volume is a curious combination which appears to consist of the author's opinions and conclusions based on personal experience and memory of past reading. There are no references or other acceptable support appended. One example, among many, of careless writing is a statement on page 80 that John Snow used "carbon dioxide absorption" about 1887, whereas Snow had been dead nearly thirty years at that time. Perhaps the author explains his book when he says in the preface that "It is written only as an account of practical experiences gleaned by one who has found in anaesthetics more a hobby than a profession." The result is scarcely safe reading for students or inexperienced anesthetists. On the other hand, the vivid descriptions and definite views, as well as the stress on the humanitarian aspect of the specialty, will make Dr. Parry-Price's book valuable and diverting to many readers. The following gem quoted from page 25 is very characteristic:

"Probably the sensations under gas are more pleasant than under any other anaesthetic. Much appears to happen in a short time. One patient vividly described his sensations. He said: 'I took some deep breaths and found myself going down a long dark tunnel. I came out the other end and found myself in a lovely Devon lane. There was beautiful sunshine and a smell of hay and honeysuckle. I found myself with a wonderful maiden, and stopped in a gateway. I had just got both arms around her neck when a voice said "Now spit." ' "

Aspects pathologiques du fond de l'œil dans les affections de la rétine. Par Gabriel Renard, professeur agrégé à la Faculté de médecine de Paris, Paris. Atlas ophtalmoscopique, I. Rapport présenté à la Société française d'ophtalmologie le 21 mai 1946. Paper. Price, 1000 francs. Pp. 170, with illustrations. Masson & C^ie^, 120 Boulevard Saint-Germain, Paris 6^e^, 1946.

From 1936 to 1940 the French Society of Ophthalmology sponsored the publication of a series of excellent ophthalmologic monographs prepared by its members. It is a pleasure to welcome the reappearance of this series. The ophthalmic atlas number 1 is up to prewar standard in printing and illustrations. The author has selected a number of retinal conditions for complete study and has not attempted to cover the entire ground of ophthalmoscopy. In doing so, he has been able to correlate well the clinical findings with the ophthalmoscopic and histopathologic studies that are pertinent and profitable to the reader.

The Ship's Medicine Chest and First Aid at Sea. Completely revised as a joint project of the United States Public Health Service and the War Shipping Administration. Miscellaneous Publication No. 9. Cloth. Pp. 498, with 134 illustrations. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1947.

This is a book for people on ships without doctors. It has been revised many times since it was first developed in 1881. It contains a lot of useful information, with some help in diagnosing common infectious diseases as well as those that appear in the tropics, and it supplies the minimum of necessary knowledge regarding treatment. Special sections deal with sending medical advice by radio, birth and death at sea, medical relief of merchant seamen and the rules regarding the quarantine and control of narcotics. It must be tough to be a sailor sick on a ship where there is no doctor, even with this book to help.

An Introduction to Personal Hygiene. By Laurence B. Chenoweth. Cloth. Price, $2.50. Pp. 345, with 80 illustrations. F. S. Crofts & Co., Inc., 101 Fifth Ave., New York 3, 1947.

This textbook for college students is competent and constructed along new lines. An introductory chapter reviews the history of hygiene and sanitation; then comes consideration of the development of the human body, nutrition, the glands, the mind, mental hygiene and finally disease and the promotion of health. An excellent glossary makes easy the acquiring of enough medical vocabulary. Presumably the student who follows this course will have had some previous education in chemistry, philosophy and at least biology. The illustrations are for the most part unimportant and badly reproduced.

Probleme des Selbstmordes. Von Dr. Med. Fritz Schwarz, Professor für gerichtliche Medizin an der Universität Zürich. Paper. Price, 9.80 Swiss francs. Pp. 128, with 21 illustrations. [Distributed in U. S. by Grune & Stratton, Inc., 381 Fourth Ave., New York 16.] Hans Huber, den Marktgasse 9, Bern 16, 1946.

This monograph deals largely with certain statistical, medicolegal and sociologic aspects of suicide in Europe and particularly in Switzerland between 1900 and 1940. A wealth of case material available to the author in his capacity of professor of legal medicine at the University of Zurich is the principal basis of his discussion of the extrinsic and intrinsic factors that predispose to self destruction and of the various methods employed for its accomplishment. The book has been prepared for readers whose interest in the subject is broad and superficial rather than for the sociologist, the psychiatrist or the medicolegal expert in search of detailed and specialized information.

Public Baths and Health in England, 16th-18th Century. By Charles F. Mullett. Supplements to the Bulletin of the History of Medicine, No. 5. Paper. Price, $1.50. Pp. 85. Baltimore: The Johns Hopkins Press, 1946.

The student of physical medicine as well as the medical historian will be repaid by reading this informative and at times highly diverting monograph on the relationship between health in England and the development of English spas during some two hundred years between the sixteenth and eighteenth centuries. The author has presented his subject in the form of a bibliographic essay, the preparation of which required a critical review of 470 references. Of these, 414 appeared in popular or technical publications between the years 1660 and 1880. Such a mass of literature shows the interest which the therapeutic use of "waters" and bathing excited in England during that period.

By drawing on this font of contemporary literature the author has succeeded in presenting an excellent picture of the conduct and uses of the various well known English baths of that day. Furthermore, he has furnished an interesting account of the way of life as well as the opinions and beliefs, both lay and medical, on matters of health and bathing that obtained during that period in England. The frequent introduction of amusing anecdotes and quaint observations enlivens an essay that represents extensive thoughtful research and is an instructive contribution to the literature of balneology.

DeLee's Obstetrics for Nurses. By M. Edward Davis, M.D., Professor of Obstetrics and Gynecology, University of Chicago, Chicago, and Mabel C. Carmon, R.N., Chief Supervisor and Instructor in the Birthrooms of the Chicago Lying-In Hospital and Dispensary, Chicago. Fourteenth edition. Cloth. Price, $3.50. Pp. 640, with 338 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5; 7 Grape St., Shaftesbury Ave., London W. C. 2, 1947.

This work has been so polished by revision that it is wellnigh perfect. Among the especially commendable features are the excellent photographs of deliveries which were obtained from motion picture films, the superb colored plates and the judicious use of antique pictures of obstetric procedures in earlier centuries. The style of the volume is well calculated to hold the interest of student nurses, yet the contents fulfil the requirement of the graduate nurse concerned with minutiae of technic. Each chapter is followed by questions for review, which serve to remind the lazy reader of the important points in the text. A handy glossary, printed on green paper for convenience, is appended, and the index is adequate. As might be anticipated, the book emphasizes only the methods used at the Chicago Lying-In Hospital, but these methods are so sound that few will take exception to them. The volume is recommended to all nurses, undergraduate, graduate or supervising, who manage obstetric patients.

Advances in Pediatrics. Volume II. Editorial Board: S. Z. Levine, Cornell University Medical College, New York, Allan M. Butler, Harvard Medical School, Boston, L. Emmett Holt, Jr., New York University, College of Medicine, New York, and A. Ashley Weech, University of Cincinnati, College of Medicine, Cincinnati. Cloth. Price, $6.75. Pp. 409, with illustrations. Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1947.

This volume considers fluorine in dental caries, virus diarrhea, atypical pneumonia, chemotherapy and rheumatic fever. The book is designed to help pediatricians to keep abreast of current advances in the subjects concerned.

Psychiatric Research: Papers Read at the Dedication of the Laboratory for Biochemical Research, McLean Hospital, Waverley, Mass., May 17, 1946. By Cecil K. Drinker and others. Harvard University Monographs in Medicine and Public Health, Number 9. Cloth. Price, $2. Pp. 113, with 7 illustrations. Harvard University Press, Cambridge 38, Mass.: Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1947.

Six papers read by distinguished scientists at the dedication of the laboratory for biochemical research at McLean Hospital, Waverley, Mass., are presented in this small book. Dr. Drinker of Harvard University reviews the history of research at the McLean Hospital, a history made meaningful by such names as Folin, who undertook biochemical investigations in mental disease at the beginning of the century. Dr. Folch's paper on Biochemical Problems Related to Psychiatry is a masterly and fascinating survey of brain function as studied by the biochemist. Stanley Cobb contributes a report on progress in the integration of medical and psychiatric problems. Dr. H. S. Gasse, director of the Rockefeller Institute for Medical Research, presents a scholarly paper on the language of science. A paper on Psychical Seizures by Dr. Wilder Penfield, director of the Montreal Neurological Institute, and discussion of the Psychobiology of Psychiatric Research by Dr. Strecker complete this remarkable collection. This small volume offers in compact form meaty reading that should have the attention of every psychiatrist and every student of behavior.

Science Advances. By J. B. S. Haldane. Cloth. Price, $3. Pp. 253. The Macmillan Company, 60 Fifth Ave., New York 11, 1947.

The majority of the essays included in this book have appeared in British scientific publications. The author admits that he is a Marxist, and he is convinced that Marxism is the best application of the scientific method to the widest field so far achieved by man. Many of his essays appeared in the *Daily Worker*. Professor Haldane writes exceedingly well. When he is writing on any subject other than Marx and his political doctrines or Russia, which is one of his great admirations, he is well worth reading.

L'électro-choc et la psycho-physiologie. Par Jean Delay, professeur agrégé à la Faculté de médecine, Paris. Paper. Price, 230 francs. Pp. 171. Masson & Cie., 120 Boulevard Saint-Germain, Paris, 6e, 1946.

This is an important and much needed discussion of electric shock in its therapeutic and theoretic aspects. The author is one of the outstanding research men in France today, and has done considerable work in this field. He discusses the epileptic attacks under electric shock treatment in a descriptive and dynamic sense. Of particular significance is his consideration of the effect on diencephalic function as it influences humoral changes. This study does not limit itself to the physiologic and biochemical side but also considers the effects of shock on consciousness and the mental functions. It is an extremely valuable book for all persons using this technic.

Advances in Internal Medicine. Volume II. Editors: William Dock, M.D., Long Island College of Medicine, Brooklyn, N. Y., and I. Snapper, M.D., the Mount Sinai Hospital, New York, N. Y. Associate editors: Tinsley R. Harrison, M.D., Southwestern Medical College, Dallas, Texas and others. Cloth. Price, $9.50. Pp. 642, with illustrations. Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1947.

This book is essentially a collection of articles on problems of current interest in medicine. Among the subjects covered are hypertension, the Rh factor, the uses of penicillin and nutritional requirements in disease. For those who wish to be brought up-to-date in these fields, the book may be well recommended because of its authoritative character.

The Proceedings of the Charaka Club. Volume XI. Boards. Price, $7. Pp. 243. Published for the Charaka Club by Richard R. Smith, 120 East 39th St., New York 16, 1947.

Essays here collected include contributions from such distinguished writers as Fred B. Lund, Edward L. Keyes and Peyton Rous. The biographies of Casey Wood, Walter Ralph Steiner, William Osler Abbott and Bernard Sachs are reminiscent of these great American physicians. The eleven volumes of essays included in the transactions of the Charaka Club are a part of American medical history. As one reads the list of members in 1946, one wonders how the present membership is building for the future.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MULTIPLE SCLEROSIS

To the Editor:—Since chemotherapy and the antibiotics have come into such a wide range of usefulness, have any of these agents been of benefit in the treatment of multiple sclerosis? The patient is a young married woman, a primipara, aged 27. Her child is over 2 years of age. The patient's first symptoms occurred a year ago, with numbness on the left side of the face, disturbance of vision and nystagmus. Later she had motor disturbances, scanning speech, paraplegia, dysuria and numbness in various parts of the body. These attacks last about three or four weeks and recur in some form about every eight or ten weeks.

W. G. Shallcross, M.D., Pittsburgh.

ANSWER.—Chemotherapy and the use of antibiotics have not been shown to be of value in the treatment of multiple sclerosis. As no specific treatment of the disease is known, the chief features of the present day care consists of morale building as a means of dealing effectively with anxiety, the prevention of the precipitating factors, rehabilitation and symptomatic relief. Factors leading to relapses are now thought to be infections, unfavorable climate, pregnancy, fatigue, poor nutrition, emotional disturbances and chilling. In rehabilitation physical therapy, including massage, hydrotherapy and exercise, is of importance. Various drugs are now being investigated, such as curare, neostigmine, racemic amphetamine sulfate, dextro-amphetamine sulfate ("dexedrine"), diphenhydramine ("benadryl") and vitamins; none appears to have any specific action on the disease. Constipation and urinary disorders require special care; urinary infections should be rigorously combated.

Treatments aimed at overcoming infections, bacterial or viral, have been largely abandoned. The antibiotics, arsphenamine and fever therapy are no longer used. The newer attacks are based on the various theories of the cause of the disease. "Dicumarol" is used to combat the possible thrombosis of venules, and vasodilator drugs, particularly amyl nitrate and papaverine hydrochloride, are used to reduce the vascular spasm, thought by some to be a factor in developing the disseminated lesions. Along similar lines, histamine has been given a wide trial without fully accepted results. Sympathectomy as a form of treatment has been largely abandoned. Because remissions and relapses occur in the natural course of the disease, evaluation of any therapy is difficult. All forms of treatment are in the experimental stage. The National Multiple Sclerosis Society has recently been formed for the study of the disease and the advancement of research.

OCCUPATIONAL DERMATITIS DUE TO PENICILLIN

To the Editor:—I have received penicillin twice in the last two years. Last June I had an infected vein in the right leg and took 500,000 units of penicillin in two days. Nine days later there developed dermatitis due to penicillin on my feet, legs, hands, arms and face. I took 50 mg. of "benadryl" and "pyribenzamine," which cleared it up in a few days. Whenever I give penicillin to patients the dermatitis develops again. This has now gone on for two months. Use of gloves and salve on my hands is without effect. Can I be desensitized?

C. W. Johnston, M.D., Jacksonville, Fla.

ANSWER.—Desensitization for contact type of dermatitis due to penicillin is theoretically possible. The final outcome, however, is rather dubious, since your degree of sensitivity is exceptionally high. Hypodermic injections of solutions of penicillin, probably beginning with 0.05 cc. of a solution with a concentration of 10 units per cubic centimeter, given three times weekly, and increasing the dosage as one does in desensitization to pollen should be tried. After the 1 cc. volume is reached the next strength of 100 units per cubic centimeter can be used. Then in sequence 1,000, 10,000 and 100,000 units per cubic centimeter can be employed. During treatment a constitutional reaction consisting of dermatitis is possible if the dose is too great. If this happens the dose should be reduced. If the foregoing procedure is regarded as too tedious or is unsuccessful, the simple expedient of anointing the skin with an ointment of tripelennamine ("pyribenzamine") hydrochloride (Feinberg, S. M., and Bernstein, T. B.; Tripelennamine "Pyribenzamine" Ointment for the Relief of Itching, *J.A.M.A.* **134**:874 [July 5] 1947) before and after the use of penicillin may be of some benefit.

EYELID EDEMA

To the Editor:—A white man, aged 26, complained of a burning sensation in the eyes, photophobia and lacrimation for fifteen years. He had consulted many ophthalmologists, who prescribed various drops, ointments and glasses, without relief. Physical examination revealed a well nourished young man, extremely nervous, who was so "ticklish" that it was difficult to perform a complete abdominal examination. He also had a nonspecific urethritis with a watery urethral secretion which was bacteriologically negative. The patient admitted having gonococcic infection some years ago. Examination was otherwise negative. His eyes were red, with scaly lids, and he had chronic blepharoconjunctivitis, the lids being stuck together nearly every morning. The pupils were regular and reacted to light. Dulness of the cornea was absent. Fundic examination revealed normal conditions except for moderately dilated veins. Vision was 10/10 in both eyes. A basal metabolic test was performed because of his nervousness. The rate was minus 26 per cent. I made a temporary diagnosis of localized myxedema (swelling of lids) and prescribed thyroid extract ½ grain (30 mg.) three times a day. Within three weeks all ocular symptoms had disappeared. Lids were no longer swollen, no more scales were observed. Conjunctivitis had disappeared as well as the excess lacrimation. A control basal metabolic test revealed a rate of minus 12 per cent. I have seen the patient recently and he continues to be well. Do many cases occur resembling this one, in which hypothyroidism appears to be the basis of ocular troubles?

M.D., Canada.

ANSWER.—Cases of lid edema with low basal metabolic rates due to thyroid deficiency have been reported. Weiss and King reported such a series in the *Ohio State Medical Journal* for May, 1932.

The redness of the lid margins and the conjunctivitis may be on an allergic basis. Even puffiness of the lid may be caused by allergies.

HORMONES FOR IMPOTENCE AND DYSMENORRHEA

To the Editor:—Please discuss the use of each of the following substances in impotence, so-called hypogenitalism and dysmenorrhea: testosterone propionate, gonadotropic hormone from pregnant mare serum, such as "anteron," and chorionic gonadotropic hormone from pregnancy urine, like "pranturon." What are the eventual dangers of each of the substances in young men and women? Which gives more lasting results in impotence or hypogenitalism? Which should be used for impotence in men of ages 40 to 50. What is the danger of formation of antihormones? Does testosterone cause atrophy of the testicle or of the germinal epithelium after repeated or prolonged use? What are the carcinogenic influences of these substances? Does pregnant mares' serum used for dysmenorrhea month after month cause adverse effects in the ovaries of young women?

M.D., New York.

ANSWER.—In treatment of dysmenorrhea glandular medicaments may be of value. It should be remembered, however, that in most cases of functional dysmenorrhea the ovaries are quite normal and that endocrine therapy for relief from the pain coincident to menstruation is usually designed to suppress ovarian function. Testosterone propionate is effective either by suppressing ovulation and corpus luteum formation or by partially neutralizing the secretions of the corpus luteum and thus diminishing the stimulus for uterine contraction. It is also possible that testosterone propionate causes a direct relaxation of the uterine musculature and thereby decreases the amplitude of uterine contractions.

One other possible mechanism exists by which testosterone propionate may aid in giving relief from dysmenorrhea. Since it is accepted that functional dysmenorrhea is the result of a low threshold to pain arising from uterine contractions, anything which elevates the threshold will aid in relieving pain. Many patients with dysmenorrhea have premenstrual tension which causes them to be more sensitive to a variety of stimuli. Relief of the premenstrual tension with testosterone propionate will cause a lessening of pain. To obtain relief in dysmenorrhea, therefore, it is suggested that testosterone propionate or the oral preparation, methyl testosterone, be administered during the ten days preceding menstruation.

Chorionic gonadotropic hormone or equine gonadotropin hormone have little physiologic basis in treatment of dysmenorrhea.

In the treatment of impotence or hypogenitalism, testosterone propionate is usually the endocrine of choice. Chorionic gonadotropic hormone from pregnancy urine is effective in stimulating the testes of individuals when the testes are potentially normal but under-functioning, as in prepuberty. Under such conditions the testes can be made to secrete their natural sex hormones, thus causing maturation of the secondary sex organs and male characteristics. For this reason it is used for treatment of functional cryptorchidism. In most cases of hypogenitalism in the adult this material is ineffective. Equine gonadotropin does not appear to have any advantage over chorionic gonadotropin for the identical conditions.

In the treatment of impotence, one must distinguish between psychic, organic and senile impotence. In the first condition varying amounts of psychotherapy may be effective, action of medication being mainly through suggestion. In senile impotence no endocrine material is of value because of the lack of erectile tissue function. Where impotence is due purely to a lack of male sex hormone, testosterone propionate is a specific substance. No antihormones develop from this material, and danger of organic harm in men treated with this material in the therapeutic dosages even though administered over long periods of time is no greater than that induced by functioning testes. Testosterone may cause atrophy of the testes with suppression of spermatogenesis, but normal tubular function returns after cessation of therapy.

Little evidence exists as to carcinogenic effects, the doses ordinarily used in human cases apparently do not have such effects. The administration of the gonadotropins if continued over long periods of time may occasionally produce deleterious effects on the ovaries. These organic changes are chiefly limited to the development of cysts in the ovaries and may result in disturbances of menstruation. The formation of antihormones by the gonadotropins is possible, and if these develop there is resistance to further therapy, although no eventual harm results from the formation of the antihormones.

FLUORINE IN DENTAL CARIES

***To the Editor:*—What information exists relative to uses and dangers of fluoride? My 4 year old child is developing cavities in his teeth despite balanced diet, milk, cod liver oil in capsules or Lilly's Homicebrin capsules. Would you advise using the tablets or lozenges of "Enziflur?" What other suggestions are you able to give? Please discuss the use of fluorine in adults.**

M.D., Oklahoma.

ANSWER.—There is no acceptable adequately controlled scientific evidence that would indicate that the intensity of dental caries attack in a 4 year old child can be markedly inhibited by balanced diet, milk, cod liver oil in capsules or Lilly's Homicebrin. In respect to the use of "Enziflur," an editorial in the *Journal of the American Dental Association* (**34**:345-346, March 1, 1947) states in part: "Strean and Beaudet (Strean, L. P., and Beaudet, J. P., Inhibition of Dental Caries by Ingestion of Fluoride-Vitamin Tablets, *New York State J. Med.* **45**:2183 [Oct. 15] 1945) have reported some lessening of caries activity in children receiving daily supplements of 3 mg. of calcium fluoride for periods of six to eight months. This study is not conclusive because it is based on totally inadequate data to support the claims made. Until more convincing data are presented, therefore, the use of fluorides in dentifrices, mouth washes, tablets, and lozenges cannot be recommended."

If cavities are developing rapidly the intake of refined sugars should be sharply curtailed and consideration given to the topical application of a 2 per cent solution of sodium fluoride immediately after a prophylaxis by a dentist.

The evidence in respect to the use of fluorides for control of dental caries in adults is so limited and inconclusive that a statement as to whether it will or will not reduce the incidence of dental caries is largely conjectural.

BELYANDO

***To the Editor:*—A patient's chief complaint consists of two or three spasmotic paroxysms of vomiting before breakfast. Occasionally a slight amount of mucoid material is raised. Other associated symptoms are absent. He stated that such a condition is commonly experienced in Australia and Queensland during the summer season and recurs among the native whites seasonally, being termed "Barcoo spew" or "belyando." Is there information available concerning the etiology, pathogenesis and treatment of this condition?**

M.D., Florida.

ANSWER.—Barcoo spew is defined by medical dictionaries as nausea, vomiting and sometimes bulimia encountered in the upland region of the Barcoo River of southern Australia. Its cause appears to be unknown. A similar syndrome was observed in military personnel during World War II, associated often with nervousness, dissatisfaction with the rough life and perhaps some gastritis. Prebreakfast nausea and vomiting will make the physician think of chronic alcoholism, achlorhydria, chronic tuberculosis, an unsatisfactory diet or a neurosis. Occasionally early morning rumbling in the abdomen, gas and perhaps vomiting will be due to eating too large a supper or eating some food to which the patient is allergic. Such an etiologic basis may easily be tested for by having the patient go without any supper for a few evenings. If this brings relief, one food can be taken each evening until it is determined which are the harmless and which are bad. If there is achlorhydria, ½ teaspoon dilute hydrochloric acid can be taken in a large glass of water with meals. If this does not help promptly it should be stopped. A smooth nonirritating type of diet can be tried. If the patient is drinking, smoking or eating too much these habits should be moderated. If there are signs of a neurosis or mild psychoneurosis that problem should be investigated.

Obviously, before treatment is started the stomach and gallbladder should be examined roentgenologically. A diaphragmatic hernia should be looked for by the physician.

ANESTHESIA IN OBSTETRICS

***To the Editor:*—What are the present dangers and complications of caudal analgesia? How does caudal anesthesia compare with the conventional types of obstetric anesthesia, such as "demerol" and scopolamine followed by ether or gas and ether? What are the statistics on the respective maternal and fetal mortality and morbidity?**

Rudolph Joseph, M.D., Freeport, N. Y.

ANSWER.—Caudal analgesia is not used as much today as formerly. Reasons for this are the possibility of major and minor complications, the necessity for a specially trained group of obstetricians and anesthetists and the present use of low spinal and saddle block anesthesia. It is difficult to give exact figures for maternal and fetal deaths for either caudal analgesia following meperidine ("demerol") and scopolamine or other forms of anesthesia following these analgesic drugs. In a recent article on "Anesthesia in Obstetrics," J. P. Greenhill (*Am. J. Obst. & Gynec.* **54**:74-81 [July] 1947) makes the following statement about caudal analgesia: "In my opinion there is no more satisfactory and pleasant type of analgesia in obstetrics than this procedure (caudal analgesia) when it is performed properly without a mishap. However, because of the definite though slight risk of death and the chance of producing a minor or a major complication, continuous caudal analgesia has a limited field of usefulness. It is definitely a hospital procedure and should be used only in those hospitals which have a large and sufficiently experienced personnel. This personnel should not only be experienced in obstetrics and anesthesia, but also specifically trained in administering caudal analgesia. Likewise, this personnel must have the time and the willingness to be in constant and vigilant attendance on women who are given this type of anesthesia. Furthermore, resuscitation apparatus must be available for instant use and personnel trained in its employment. Because of the possible dangers and complications, the trained personnel and apparatus required and the high cost of this type of anesthesia, there is no need to use it for the average woman in labor. Most of the pains of labor, which are quickly forgotten in any event, can be relieved by less hazardous drugs and anesthetics."

In table 2 (arranged from Trent and Gaster, *Ann. Surg.* **119**: 954, 1944) of his article, Greenhill presents these data:

Anesthetic	Number of Anesthesias	Anesthetic Deaths	Number per 1,000 Anesthesias
Local	13,151	0	0
Ether	14,724	6	0.407
Nitrous oxide	6,705	2	0.295
Nitrous oxide with ether	2,175	2	0.919
Cyclopropane	5,744	4	0.691
Spinal	5,436	6	1.100
Spinal with supplement	930	2	2.150
Total	54,128	22	0.498

Concerning the effect of anesthetics on the baby, Greenhill says: "Local infiltration anesthesia has absolutely no deleterious effect on the baby. Likewise, caudal and spinal anesthesia do not affect the baby adversely except in the few cases where there is a precipitous drop in blood pressure. On the other hand, the inhalation anesthetics have been responsible for the deaths of some babies. In most cases it is probable that the analgesic drugs given to relieve the pain of the first stage plus the anesthetic administrated for delivery caused the fetal casualties; but inhalation anesthetics by themselves have caused deaths of newborn babies. Inhalation anesthetics are particularly dangerous for premature babies and babies whose mothers have diabetes and other complications."

ZINC CONTENT OF LEUKEMIC CELLS

***To the Editor:*—I have heard rumors of a new method of treating the leukemias, especially chronic leukemia, by the use of zinc. I have been unable to obtain information on this matter and do not even know what clinic has been doing the work. What information is available?**

R. H. Johnstone, M.D., Chicago.

ANSWER.—Studies on the zinc content of leukemic cells were reported at the recent meeting of the fourth Congress of International Cancer Research. The studies were performed by Dr. John G. Gibson and his associates, Boston, and indicated that the zinc content of white cells was decidedly decreased in both lymphatic and myelogenous leukemia. The plasma values were within the normal range, but red cell values tended to be above normal.

Following urethane therapy in 1 case of myelogenous leukemia, the white cell zinc unit value was observed to rise. Studies with radioactive zinc suggested that mobilization and utilization of zinc was more effective during a period of decline of the white blood cell count. The authors estimated that the daily intake of new zinc in a case of subacute myelogenous leukemia under observation was 2 mg. per day. Doses in excess of this amount failed to raise the white cell unit value of zinc to normal limits, nor was the white count significantly altered. Comments were not made by the authors as to therapeutic application of these observations.

PENICILLIN - AEROSOL

To the Editor:—I should like some information on penicillin aerosol. On a recent trip to Baltimore I saw it used in a doctor's office and he seemed to be treating a great number of cases of purulent infections of the upper part of the respiratory tract. The articles I have read in *The Journal* show apparatus which does not appear to be as satisfactory as what I saw in Baltimore. This particular device had several pressure gages, and the solution was forced through nasal cannulas using a regular electric pump instead of an oxygen tank. I was told that it employed both negative and positive pressure, thus evacuating air from the sinuses and replacing it with the penicillin mist. What is the consensus at present in regard to the merits of penicillin aerosol? What are its harmful effects? What apparatus is considered best, and where can it be obtained?

M.D., Tennessee.

Answer.—The results of the use of penicillin aerosol together with the various types of apparatus that are useful have been reported by Garthwaite, Barach and their technical assistants. It was their opinion that antibiotic aerosol therapy constituted an effective and practical technic which may be added to other orms of therapy in the management of patients with bronchopulmonary suppuration. The cases included bronchiectasis, acute and chronic abscess of the lung and chronic bronchitis. In addiion to these cases they have reported some favorable results in he treatment of chronic sinusitis.

DIABETIC TEETH

To the Editor:—Is there any characteristic staining of or significant changes in teeth of diabetic persons?

M.D., Pennsylvania.

Answer.—There is no characteristic staining of the teeth of diabetic persons and no significant changes in the teeth that can be attributed to diabetes alone. Diabetic persons in coma or severe acidosis will have dehydrated, cherry-red oral mucous membranes with loosening of teeth. These changes disappear on treatment.

Greater susceptibility to caries, pyorrhea and deposits of tartar about the teeth are associated with but are not consistently characteristic of diabetes mellitus.

COTTONSEED

To the Editor:—A patient whom I recently skin tested was sensitive to cottonseed. In what common foods and materials does this item occur?

M.D., Illinois.

Answer.—Cotton seed oil may be used in the preparation of margarine, salad oils, vegetable shortenings, mayonnaise, sandwich spreads and other related products. Parts of the seed when finally ground are used in certain breads and bakery goods. Thus in order to avoid foods containing cotton seed products, it is necessary to prepare foods at home or to use only those of known origin.

SKIN IRRITATION FROM ILEOSTOMY

To the Editor:—What are the latest protecting applications used on the skin surrounding the stoma of an ileostomy.

Jean Spencer Felton, M.D., Oak Ridge, Tenn.

Answer.—The best treatment for irritation of the skin surrounding the stoma of an ileostomy is prevention. This can best be accomplished by the use of a Koenig-Rutzin cup. This is applied by rubber cement to the skin and thoroughly excludes the skin from irritation. If the skin is irritated, it must be brought back to normal before the cup can be applied. This is best accomplished by putting the patient in prone position for twenty-four hours, allowing the ileostomy discharge to drain into a basin so that the skin will be entirely free. The skin can also be covered with an aqueous solution of methylrosaniline chloride (gentian violet), which hardens it and aids in the healing of the abraded areas.

A new technic includes the bringing of the intestine well out of the opening and surrounding it with a skin graft.

STREPTOMYCIN IN TUBERCULOUS PERITONITIS

To the Editor:—Has streptomycin been used in treatment of tuberculous peritonitis?

M.D., Canada.

Answer.—Streptomycin has been used on isolated cases of tuberculous peritonitis in several institutions, but an adequately large series of cases has not been observed by any one physician to permit a clinical appraisal of the value of streptomycin in the treatment of this condition. Accurate diagnosis of tuberculous peritonitis ordinarily is obtained only by abdominal exploration or peritoneoscopy. Prompt clinical improvement is frequently experienced following such diagnostic procedures. Other methods of treatment initiated at this time might be given credit for such spontaneous improvement. All reports of the therapeutic effects in tuberculous peritonitis should therefore be viewed with reservations.

DEATH IN A WELL

To the Editor:—A patient aged 52, never strong, went down an open well 45 feet deep to clean it. A few minutes after reaching the bottom he said, "I am coming out." Before he could get up he slumped over. He was dead when removed. Before descending the well a lantern that he let down continued to burn. After pulling the man out the lantern was again let down. It still continued to burn. A canary bird placed in the well died in two minutes. A pigeon remained in the well fifteen minutes—in good condition. Did the man die from carbon monoxide? He had had a heart attack five days before he died. Could it be that the exertion of going down killed him?

E. N. Powell, M.D., Corydon, Ky.

Answer.—Death was in all probability due to the heart condition from which the patient was known to be suffering.

When death occurs from poisoning with carbon monoxide, it is not so sudden. It is preceded by a regular sequence of events, beginning with dizziness and followed by headache, weakness, drowsiness, stupor and unconsciousness, This is usually followed by convulsions, muscular rigidity and death due to cardiac arrest. Death was too sudden for carbon monoxide poisoning.

TONSILLECTOMY IN PREGNANCY

To the Editor:—Is tonsillectomy contraindicated in the early months of pregnancy? A young woman in the first month of pregnancy aborted two months after a tonsillectomy performed with the patient under local anesthesia. Her physician believes that the tonsillectomy was the cause of her abortion in spite of the interval of two months. M.D., Arizona

Answer.—Tonsillectomy with the patient under local anesthesia is not contraindicated during the first trimester of pregnancy if the indications for the procedure do not permit delay until after delivery. In general it is better to postpone elective surgical procedures of this type. Abortion two months after tonsillectomy is difficult to relate to the operation.

PENICILLIN ARTHRALGIA

To the Editor:—After a sailor, aged 22, received 7,000,000 units of penicillin for primary syphilis there developed urticaria and erythema multiforme, polyarthropathy consisting of tender, reddened, painful ankles, knees, wrists and elbows. The administration of penicillin was stopped immediately, and "benadryl" was started. The allergic cutaneous manifestations and articular symptoms subsided promptly; however, pains and aching have persisted in the knees for two months. There was a history of transient pains in the joints several years ago. Can the persistent symptoms in the knee joints be explained on an allergic basis?

Lieutenant (MC), U.S.N.R.

Answer.—The arthralgias that occur during the course of penicillin hypersensitivity are self limited and last for only a few days to two weeks. In view of the history of transient pains in the joints several years prior to treatment with penicillin look for other causes to explain the persistent arthralgias. It is impossible to state whether the persistent symptoms in the knee joints can be explained on an allergic basis, and certainly it would be most difficult to prove.

PROGRESS IN BRONCHOLOGY

LOUIS H. CLERF, M.D.
Philadelphia

The physician who entered the field of medicine twenty-five years ago either was unfamiliar with bronchoscopy or associated it only with removal of foreign bodies which had become wedged in the air passages. These accidents were considered as rare medical curiosities, and as a result few physicians actually witnessed a bronchoscopic procedure. Now, a quarter of a century later, bronchology is a recognized specialty in medicine, and practically every large hospital has a well organized bronchoscopic clinic.

Originally designed and perfected for the removal of aspirated foreign bodies, bronchoscopy now is employed as an aid either in diagnosis or in treatment of practically all bronchopulmonary diseases associated with bronchial obstruction or with an increase of bronchial secretions. The scope of its uses has exceeded the original concepts so that its relation to certain fields of medicine and surgery can be considered as on a par with that of roentgenology. While about 25 per cent of the bronchoscopies performed in the few bronchoscopic clinics in existence a quarter of a century ago were done to remove foreign bodies from the air passages, now in the many hundreds of clinics established over the entire United States, as well as in foreign countries, less than 2 per cent of all bronchoscopic procedures are performed for this purpose. The occurrence of foreign body accidents has not diminished, but the number of cases is overshadowed by the enormous group of bronchopulmonary diseases requiring bronchoscopic study and treatment.

No chapter of modern medicine is more interesting or more conspicuous than that contributed by bronchology concerning the symptoms, the pathologic aspects, the diagnosis, the prognosis and the treatment of foreign bodies in the air passages. In the days of Samuel D. Gross, the mortality rate of surgical attempts to remove foreign bodies from the air passages was over 27 per cent. Failures were common, and in these pulmonary suppuration with chronic invalidism was the usual outcome. In our larger bronchoscopic clinics, where there are available records of many hundreds of cases of foreign bodies in the air passages, the mortality rate is less than 1 per cent, and failures are rare.

Bronchology has added enormously to knowledge of the function of the tracheobronchial tree. It has contributed information concerning obstructive emphysema and atelectasis and the interpretation of physical signs. In the diagnosis of bronchopulmonary disease it has become a valuable aid to the internist. It has aided materially in the progress made in the fields of thoracic surgery and anesthesiology. In dealing with the problems of respiratory obstruction, the anesthesiologist has become familiar with the methods of the bronchologist. He has utilized to a great extent the equipment commonly employed in the field of bronchology.

A detailed account of all the contributions made to medicine and surgery in the field of bronchology, as well as of the numerous contributors, would exceed the allotted time and space of this presentation. Reference therefore will be made to the more recent advances and to the present status of bronchology in diagnosis and treatment.

BRONCHOGENIC CARCINOMA

Until two decades ago a diagnosis of carcinoma of the bronchus usually was made by the pathologist in the autopsy room. This procedure was slowly replaced by bronchoscopic biopsy, with a positive diagnosis of the lesion in the living patient, and as a result opportunity was given thoracic surgeons to evolve a technic for the successful removal of the entire lung for carcinoma. The increasing interest taken in carcinoma by the general practitioner and the internist has resulted in the accumulation of clinical reports aggregating many hundreds of cases, with bronchoscopic biopsy yielding a positive diagnosis in from 60 to 80 per cent of the cases and bronchoscopic anatomicopathologic findings warranting a diagnosis of carcinoma in an additional 10 to 15 per cent of cases.

In evaluating the results of surgical treatment of bronchogenic carcinoma it soon became apparent, however, that positive bronchoscopic diagnoses, although made during life, gave too few opportunities for successful surgical extirpation of the tumor. It also became evident that, in order to treat this disease successfully, it would be necessary to make the diagnosis earlier, before larger bronchi became obstructed, and to have the search for lesions located beyond the visual field of the bronchologist brought to an earlier conclusion diagnostically.

A telescopic lens system employed as a bronchoscopic obturator for inspection of lesions "around the corner."

From the Department of Laryngology and Broncho-Esophagology, Jefferson Hospital.

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

in the bronchi of the upper lobe was added to the armamentarium, but, it provided little diagnostic assistance.

Recently cytologic studies of bronchial secretions have shown that "cancer cells" are present in the bronchi in cases of bronchogenic carcinoma. With the aid of appropriate collection tubes and aspirators, secretions may be secured bronchoscopically from the site of the suspected carcinoma, and, with special staining methods, the cells may be recognized as being neoplastic in character. It has been conclusively demonstrated in at least an additional 20 to 25 per cent of cases that carcinoma can be diagnosed positively in those whose lesions are beyond bronchoscopic vision. It also has been shown that complete surgical removal can be carried out in a higher percentage of cases in which carcinoma occurs in bronchi beyond the field of bronchoscopic vision than of the group in which the lesions are diagnosed by bronchoscopic biopsy. If this method of diagnosis could be utilized with all patients whose roentgenograms present suspicious shadows and if routine roentgenographic surveys were made of the chests of all adults who are presumably well, the outlook of the patient with bronchogenic carcinoma would be hopeful. It is a common experience to find that definite diagnostic procedures have been delayed until the disease is advanced. That is why bronchogenic carcinoma has been recognized late and why it is suitable for surgical treatment in relatively few cases.

Attempts have been made to treat bronchogenic carcinoma by endobronchial implantation of radon or by application of radium element. These have been attended by little success.

BENIGN TUMORS

While the incidence of carcinoma of a bronchus is about ten times greater than that of benign bronchial tumor, the occurrence of a tumor of the latter type must be considered in every case of bronchial obstruction. Adenoma of the bronchus, a glandular tumor, is the most common form of relatively benign growth and often is observed in young adults. Although the earlier bronchoscopic biopsies of such tumors were reported as revealing adenocarcinoma, further studies of these tumors have shown that they are definite neoplastic entities. Many patients with endobronchial benign tumors have been successfully treated by instrumental removal and diathermy carried out bronchoscopically. Adenoma often occurs as an endobronchial or an extrabronchial tumor. This usually can be demonstrated by body section roentgenography. In addition, adenoma may undergo cancerous changes. As a result, surgical extirpation must be considered in treatment.

PULMONARY ABSCESS

In the earlier days, before external surgical drainage of pulmonary abscess or lobectomy became a relatively safe procedure, bronchoscopic aspiration was an accepted therapeutic procedure in the medical management of pulmonary abscess, and many lives were saved by this means. Today, with prophylactic measures, sulfonamide compounds and antibiotic drugs, as well as surgical treatment, the trend has been away from bronchoscopy, which now has little place in the medical treatment. It still remains a valuable diagnostic aid, however, in cases of suspected bronchial obstruction complicated by pulmonary abscess.

BRONCHIECTASIS

For many years prior to the development of a safe surgical plan of therapy, bronchoscopy was employed as a palliative form of treatment for bronchiectasis. Now surgical removal of the involved pulmonary tissue is a safe procedure and should be carried out whenever possible. Bronchoscopy still has a definite place in the medical management of the patients not suitable for surgical treatment. It also is of value in the medical preoperative and postoperative care of the surgical group.

BRONCHIAL ASTHMA

While this condition commonly is a problem for the internist and the allergist, the assistance of the bronchologist often is required in both diagnosis and treatment. The role of the bronchologist therefore includes investigation of the tracheobronchial tree to rule out certain conditions that simulate asthma and to remove secretions from the air passages. Patients with foreign bodies in the air passages, even in the esophagus, not infrequently have been studied carefully from an allergic standpoint, and only later it is discovered that there was present a foreign body. One of the symptoms which commonly misleads to a provisional diagnosis of asthma is wheezing respiration. The mechanism of its production and its clinical significance often have been discussed by the bronchologist. Wheezing also is commonly a symptom of partial obstruction of a bronchus, and it is in this case that bronchoscopy is of value as a diagnostic aid and often as a therapeutic measure.

Studies of fatal cases of status asthmaticus have shown that one of the most common and important causes of death is the blocking of the larger air passages by thick, tenacious secretion. Failure to secure a satisfactory response by the accepted methods of medical treatment in cases of marked dyspnea due to accumulated secretions necessitates that these be mechanically removed by bronchoscopic aspiration. Spectacular results have been secured at times in moribund patients. It is obvious, of course, that in cases of this type little can be hoped for unless the life-saving measures are employed by one well qualified; for among bronchologists it is admitted that two contraindications to bronchoscopy are an inadequate armamentarium and a poorly trained bronchologist.

POSTOPERATIVE PULMONARY ATELECTASIS

Bronchoscopic investigation of so-called postoperative or atypical pneumonia revealed that in many cases the condition was not true pneumonia but the result of a blocking of bronchi by thick, tenacious secretions. Postoperative pulmonary atelectasis now is recognized as a definite clinical entity, and with this recognition appropriate treatment has reduced its more serious complications and sequelae to a minimum. In addition, preventive measures are carried out, so that it is of uncommon occurrence. Bronchoscopy is utilized now only in cases in which postoperative atelectasis does not respond to the more simple plans of therapy and mechanical aspiration of secretions must be resorted to. Bronchoscopic or catheteral aspiration also has a definite place in the medical management of all postoperative or post-traumatic conditions in which for various reasons the secretions cannot be coughed up from the air passages. They are well recognized procedures which have contributed greatly in decreasing morbidity and mortality.

TUBERCULOUS TRACHEOBRONCHITIS

Two decades ago it was axiomatic that bronchoscopy was definitely contraindicated in pulmonary tuberculosis. With increasing numbers of patients being subjected to diagnostic bronchoscopy because of obscure pulmonary diseases, many of those diseases were diagnosed as tuberculous, and as a result the frequent occurrence of tuberculous tracheobronchitis was discovered. It was noted further that no untoward effects resulted from bronchoscopy in the tuberculous patients. As collapse therapy, notably thoracoplasty, was increasingly employed for tuberculosis, with unfavorable postoperative results, a new impetus was given to bronchoscopy. It became apparent that the presence of bronchial obstruction interfered with collapse therapy, and preoperative bronchoscopy soon became a routine procedure. Statistical reports indicate that routine diagnostic bronchoscopic examination of all tuberculous patients admitted for treatment will show an incidence of demonstrable tuberculous tracheobronchitis of about 10 per cent. In tuberculous patients suspected of having tracheobronchial lesions the incidence varies from 25 to 30 per cent.

Since the acquisition of knowledge of this condition is recent, there still is some difference of opinion concerning the value of endobronchial treatment of these lesions. Bronchoscopic cauterization, preferably employing silver nitrate, is most often done. The most important bronchoscopic contribution, however, is the recognition of tracheobronchial lesions which, if unrecognized or uncorrected, would seriously impair the benefits of collapse therapy.

Many phthisiologists now have listed innumerable indications for employing bronchoscopy in the management of patients known to be tuberculous, and the time has arrived when but few contraindications to its being used in tuberculosis remain.

Direct inspection is always of distinct value in diagnosis. In the study of the tracheobronchial tree it must be remembered that the entire lung is not open to inspection. Bronchoscopic inspection should be considered as only one of a number of diagnostic measures and is supplementary to complete clinical and roentgenographic studies. It therefore is indicated as a diagnostic procedure in cases of pulmonary disease in which there is a diagnostic question remaining after physical examination and roentgenologic and laboratory investigations have been carried out. This includes the large group of cases of obscure chronic cough, hemoptysis and wheezing respiration as well as unexplained roentgen findings and physical signs. In any case of pulmonary disease, when there is doubt whether bronchoscopy should or should not be done, it should be done, provided there are no definite contraindications.

Positive findings are of the utmost value; negative findings usually can be considered of little importance but at times may be very important. Bronchoscopy still offers the only method of treatment of foreign bodies lodged in the air passages. It is a valuable aid in the diagnosis of obscure bronchopulmonary signs and symptoms, and its outstanding contributions at the present time lie in this field.

1530 Locust Street.

ABSTRACT OF DISCUSSION

Dr. Henry Boylan Orton, Newark, N. J.: It is indeed a privilege to discuss Dr. Clerf's paper on progress in bronchology. There is little that can be added except to reiterate that which has already been said. As Dr. Clerf stated, bronchoscopy was originally for the removal of foreign bodies—and in the days of Samuel Gross there were two types of foreign bodies, as he classified them: The patients who had swallowed or inhaled a foreign body vomited or coughed it up and got well, and the others went to the autopsy table. As brought out in Dr. Clerf's presentation, the scope of its uses has exceeded the original limitations, and I agree that its relation to certain fields of medicine and surgery should be considered as on a par with that of roentgenology. In the past year I have used the bronchoscope in the treatment of bulbar lesions in 2 patients with poliomyelitis, even when they were in the iron lung, to remove secretions which the patients were unable to cough up. One important part of Dr. Clerf's paper is that relating to the cytologic study of bronchial secretions. This examination should be done in all hospitals, and all hospital laboratories should be equipped to be able to do this work, thereby diagnosing conditions of carcinoma of the lung earlier and giving the patient a better chance for surgical procedure. Too much of this work on the cell content of secretions is left to technicians or other persons in the hospital who are not thoroughly familiar with the technic. This should be remedied. Two important contraindications to bronchoscopy, as brought out in Dr. Clerf's paper, are an inadequate armamentarium and a poorly trained bronchologist.

Dr. H. J. Moersch, Rochester, Minn.: Dr. Clerf, in his usual able manner, has given an excellent presentation of the development of bronchoscopy of the past twenty-five years. He failed to mention that twenty-five years ago the bronchoscopist needed to possess, in addition to certain skill for the performance of bronchoscopy, decided eloquence, to enable him to convince his colleagues that the procedure should be carried out in cases other than those of dire necessity. Today the picture is changed, and bronchoscopy is looked on as a necessary adjunct in any well developed section on thoracic diseases and as an essential procedure in any large general hospital. Although the removal of aspirated foreign bodies still remains one of the important functions of bronchoscopy, this is not the main function of bronchoscopy at present. Bronchoscopy is of greater value and importance in the diagnosis of pulmonary disease. Such conditions as hemoptysis of unexplained origin, cough, expectoration, wheeze and unresolved pulmonary inflammatory changes always indicate bronchoscopy. The value of bronchoscopy in the diagnosis of benign and malignant tumors has been well emphasized by Dr. Clerf. However, if improvement is to be made in the diagnosis and treatment of pulmonary carcinoma, early diagnosis becomes a matter of greatest importance. Bronchoscopy enables the physician to diagnose carcinoma in approximately 65 per cent of cases. Too frequently, however, it is a late, rather than early, diagnosis. Dr. Clerf and his associates have made a distinct contribution to the solution of the problem of earlier diagnosis of carcinoma of the lung by emphasizing the importance and value of the cytologic study of secretions of the bronchial tree, which may reveal malignant cells. By this method it is possible to increase one's diagnostic acumen by perhaps 20 to 30 per cent. During the past two decades a great change has taken place in the role played by bronchoscopy in the study of tuberculosis. Two decades ago the examination was undertaken with much fear and trepidation in cases of tuberculosis, but today it is looked on as a routine procedure in the study of this disease. It will undoubtedly become of even greater importance with the advances that have been made in thoracic surgery as applied to the treatment of tuberculosis, and also with the introduction of streptomycin. Dr. Clerf has called attention to the value of bronchoscopy in the study of postoperative atelectasis and has said that bronchoscopy is of special value when this condition does not respond to other forms of treatment. I would even go a little farther and say that it should be employed as a preventive of this condition. Undoubtedly, bronchoscopy will make many more advances in the future, such as that in the study of pulmonary function.

Dr. Eelco Huizinga, Holland: I wish to congratulate Dr. Clerf on his excellent paper. His message concerning examination of the secretions is important, and that proves that great improvements in endoscopy still come from Philadelphia. I should like to mention the fact that in some of these cases in which one cannot find the lesion by looking through the bronchoscope, it is possible to do a biopsy directed by a bronchogram.

Dr. Andre Soulas, Paris, France: Bronchologic advances made during the past decade are important in the field of tuberculosis and neoplasm of the bronchus. But these advances are nowhere near as important as the progress which was made during the period between 1929 and 1935. It was during that first period that Chevalier Jackson and his school discovered and specified the syndrome of the obstruction of the bronchus. The discovery was important, with all its consequences on pulmonary pathology, this pulmonary pathology which in 1920 had not yet been defined. The period between 1920 and 1930 marks the greatest progress of bronchology, since the syndrome of obstruction of the bronchus is, and will always be, at the base of bronchology. However, I think—and it has been the object of my researches for the last ten years—that it is necessary to emphasize the pathologic aspect of the wall of the principal bronchial system. This parietal pathology, as well as the relationship between the pleural and the bronchoalveolar region and the bronchial system, must be and will be the object of most interesting researches. For all these reasons, in the future the laryngologist will be the best bronchoscopist on the one and only condition that he is familiar with the physiology and the pathology of the whole thorax, in particular, the respiratory tract.

Dr. Irving Wilson Voorhees, New York: I have had an opportunity to see at the Manhattan Eye, Ear and Throat Hospital and also at the Medical Center (Presbyterian Hospital) men at work in this great specialty which has grown so rapidly. For many years I have had the privilege to know and observe Jackson in Philadelphia and many others who have developed direct tube work. As a student and intern, I often heard of a patient "drowning in his own secretion." One seldom hears that expression these days, although it probably does occur. Dr. Clerf and Dr. Orton have both well brought out that it is a charge against every medical man to allow such a thing to happen. It occurs to me that every anesthetist should be basically trained in bronchoscopy, because some of the so-called "deaths on the table" due to status lymphaticus are not at all due to status lymphaticus, but to failure of respiration because of some obstruction—secretions, foreign body or what not. Years ago at the Manhattan, we admitted two children, brother and sister, for tonsillectomy. On my way out of the hospital, I was called back to the operating room. The little boy was back on the table, and an intern was struggling to get him to breathe. I did a tracheotomy—I was not a bronchoscopist at that time—but the child never breathed through the tube. At autopsy we found grapefruit seeds at the bifurcation of the trachea. A visitor to the ward, against all orders, had given this child grapefruit! The pulp and seed had been swallowed, regurgitated after anesthesia, then inhaled. Asphyxia might possibly have been prevented if a bronchoscopist had been there. At least the boy would have had a chance. So I think we might well recommend that all anesthetists be equipped to do an emergency bronchoscopy. In hospitals where nurse anesthetists are employed, they might also be trained to use a tube and suction until a staff bronchoscopist can be called.

United States Libraries.—The Department of State maintains U. S. Libraries in three of the other American republics as part of the program of the Interdepartmental Committee on Scientific and Cultural Cooperation: the Biblioteca Benjamin Franklin at Mexico City, the Biblioteca Americana de Nicaragua at Managua, and the Biblioteca Artigas-Washington at Montevideo. The libraries are typical American public libraries, staffed with professional American librarians and operated in accordance with standard American library practice. They provide their users with complete and accurate information about the United States, whether of a general, technical or scientific nature.—Report of the Interdepartmental Committee on Scientific and Cultural Cooperation, July 1946 to June 1947, U. S. Department of State.

STATISTICAL STUDY OF LIFE CYCLE OF 1,154 CASES OF DUODENAL ULCER

MAURICE FELDMAN, M.D.
Baltimore

Attention has frequently been focused on many phases of peptic ulcer. Although most factors in the production and life cycle of peptic ulcer are probably known, the complete picture of this condition has not been fully attained. The causes of peptic ulceration remain a debatable question. The role of acid still seems predominant in the etiology of this condition. The importance of psychogenic influences is fairly well established, but the exact mechanism in which it plays in the etiology of peptic ulcer is not definitely known. There is no doubt of its constant association in the majority of cases of duodenal ulcer.

The life cycle of duodenal ulcer usually follows a distinct clinical pattern. In many instances there are clinical variables. The clinical variations are due to the type, acute or chronic, healing, recurrences and complications. The majority of duodenal ulcers are of the chronic type. The symptoms often come on insidiously and are controlled by proper eating habits; thus the abnormal condition is not recognized by the patient.

Recent studies on vagotomy have stimulated considerable impetus on this condition and emphasized the neurogenic influences in peptic ulceration. The rising incidence of peptic ulcer has created more than a passing interest among clinicians; therefore it seemed important to determine whether this increase is actual or apparent. The greater incidence in recent years is based on the supposition that a larger number of cases of peptic ulcer were seen as a result of the war. This study, involving 7,300 gastrointestinal examinations, was made of an unselected group of ambulatory private patients of both sexes and all ages. In order to establish accurate data regarding the incidence, a ten year study was made of 1,154 cases of duodenal ulcer. These cases were divided into two five year periods: (1) prewar, 1937 to 1941, and (2) during and immediately after the war, 1942 to 1946. An appraisal of the data collected over a ten year period, with two separate psychologic periods, should give some statistical evidence regarding the cycle of peptic ulcer and materially add to our knowledge. An attempt was therefore made to establish what effect, if any, the emotional strain and overwork during the wartime had on peptic ulcers, not only on increase of the incidence, but on the recurrences and severity of the symptoms.

Of the 1,154 cases of duodenal ulcer, there were 480 cases during the prewar period and 674 cases observed during the war years. The purpose of this presentation is to determine (1) whether the incidence of duodenal ulcers increased during the war, (2) differences in the sex and age incidence in the two periods, (3) increase in prevalence of acute ulcers, (4) changes in the roentgen incidence of the ulcer niches and (5) increase in recurrences.

Read in a symposium on Peptic Ulcer before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Gastro-Enterology and Proctology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947

INCIDENCE

It is the concensus that the incidence of duodenal ulcer increased in the civilian population during the war. One would naturally expect an increase in the incidence of ulcer, because of the tremendous amount of emotional strain, tension and overwork during the war. In a ten year study approximately 7,300 persons presenting digestive disturbances were examined, 3,500 in the first five year (prewar) period, 1937 to 1941, and 3,800 in the second five year (war) period, 1942 to 1946. During this ten year period 1,154 cases of duodenal ulcer were found, an incidence of 15.8 per cent. In the five prewar years there were 480 cases or 13.7 per cent. In the second five years, during and immediately following the war, there were 674 cases of duodenal ulceration, an incidence of 17.7 per cent. These statistics revealed a slight ascending trend in the incidence of duodenal ulcer during the war period.

SEX INCIDENCE

It was of interest to determine whether the sex incidence changed during the war. There was an actual increase in the number of females examined during this period; therefore there was an apparent increase in the number of females with peptic ulcer seen during the wartime.

Table 1.—*Age and Sex*

	Male		Female		Total	
Age When Examined, Years	Group 1	Group 2	Group 1	Group 2	Group 1	Group 2
Under 10	1	1	0	0	1	1
10-19	3	13	5	3	8	16
20-29	66	103	11	17	77	120
30-39	125	190	18	36	143	226
40-49	111	139	25	30	136	169
50-59	59	85	15	16	74	101
60-69	25	24	9	5	34	29
70-79	4	10	2	1	6	11
80-89	1	0	0	1	1	1
Totals	395	565	85	109	480	674

Of the 480 persons with duodenal ulcer noted in the first five years, 395, or 82.3 per cent, were males and 85, or 17.7 per cent, were females. In the second five year group, there were 674 persons, of whom 565, or 83.8 per cent, were males and 109, or 16,2 per cent, were females. There was no statistical change in the sex incidence during the two five year periods.

AGE INCIDENCE

Table 1 shows the age and sex incidence. There is an impression that duodenal ulcer occurred in females at a later age than in males. A study of table 1 shows that a slight increase in females in the wartime group occurred in the third decade. However, there is a slight increased incidence of females in the prewar group in the sixth decade. These figures are statistically unimportant. In the whole series of cases, the age incidence in females did not differ from those of males.

AGE OF ONSET OF SYMPTOMS

The majority of persons with duodenal ulcer begin to have symptoms between the ages of 20 and 35. Often there is considerable lapse of time between the onset of the ulcer and the symptoms. A comparative study of the two groups of cases shown in table 2 does not reveal any statistical difference in the age of the patient and the first appearance of symptoms.

DURATION OF THE ULCER

The determination of the duration of the ulcer has always been a problem. In most cases it is difficult to establish the exact time of onset. Often there are few if any signs of the condition before symptoms develop that are severe enough to cause the patient to seek medical attention. Table 3 shows the duration of symptoms in 1,154 cases of duodenal ulcer. It will be noted that there was an increase in the number of cases of short duration in the second five year series.

Table 2.—*Age of Onset of Symptoms*

	Male		Female		Total	
Age, Years	Group 1	Group 2	Group 1	Group 2	Group 1	Group 2
Under 10	2	2	0	0	2	2
10-15	4	5	2	3	6	8
16-20	29	52	9	6	38	58
21-25	103	117	15	19	118	136
26-30	102	122	10	21	112	143
31-35	61	99	12	19	73	118
36-40	38	55	15	18	53	73
41-45	22	53	9	10	31	63
46-50	18	31	3	6	21	37
51-55	7	15	5	2	12	17
56-60	6	7	2	2	8	9
61-65	1	4	2	1	3	5
66-70	0	1	0	0	0	1
71-75	1	1	0	1	1	2
76-80	1	0	0	0	1	0
81-85	0	1	1	1	1	2
Totals	395	565	85	109	480	674

In the majority of cases the duration of symptoms ranged from one to ten years, the predominant period being five years. It has often been assumed that symptoms in females are of shorter duration than in males. A comparative study of table 3 reveals no significant statistical change in the duration of symptoms in females as compared with males.

Table 3.—*Duration*

	Male		Female		Total	
	Group 1	Group 2	Group 1	Group 2	Group 1	Group 2
Less than 1 mo.	4	12	1	4	5	16
1 mo. to 3 mo.	20	38	5	7	25	45
3 mo. to 7 mo.	12	31	2	7	14	38
8 mo. to 11 mo.	1	12	1	1	2	13
1 yr. to 3 yr.	57	131	18	27	75	158
4 yr. to 7 yr.	86	129	23	24	109	153
8 yr. to 11 yr.	80	76	17	17	97	93
12 yr. to 15 yr.	53	59	8	12	61	71
16 yr. to 20 yr.	46	34	7	7	53	41
21 yr. to 26 yr.	23	26	0	2	23	28
27 yr. to 34 yr.	9	6	2	1	11	7
35 yr. to 40 yr.	4	11	1	0	5	11
Totals	395	565	85	109	480	674

RECURRENCES

A significant feature of peptic ulceration is the frequent remissions and recurrences. It is important to note whether there were a greater number of recurrences during the war period than in the preceding five years. The actual reasons for the recurrences frequently cannot be determined. In fact, often the digestive symptoms may not indicate the recurrence of the ulcer, but may result from spasm and irritability of the gastrointestinal tract or from other causes. The severity of symptoms following recurrences varied.

TABLE 4.—*Recurrences of Symptoms*

	Male		Female		Total	
Number of Symptomatic Recurrences	Group 1	Group 2	Group 1	Group 2	Group 1	Group 2
0	51	144	11	21	62	165
1	135	247	29	51	164	298
2	85	90	18	21	103	111
3	69	49	15	9	84	58
4	24	21	7	5	31	26
5	10	4	2	2	12	6
6	12	6	3	0	15	6
7	1	0	0	0	1	0
8	6	2	0	0	6	2
9	0	0	0	0	0	0
10	2	1	0	0	2	1
11	0	0	0	0	0	0
12	0	1	0	0	0	1
Totals	395	565	85	109	480	674

Information on this topic is difficult to obtain because the disease characteristically shows a periodicity with remissions and recurrences. Nevertheless an attempt was made to determine the number of recurrences of symptoms occurring in the two five year periods. In this study only those cases revealing clearcut recurrences of the ulcer symptoms were considered. The number of symptomatic recurrences of ulcers are charted in table 4.

There were 227 cases of "acute" ulcers, 62 occurring in the first five year series and 165 in the second five year period. In the comparative study of this chart it will be noted that in addition to the increased number of acute ulcers observed during the war period, there was also a significant increase in the first recurrence of symptoms.

ACTIVITY OF THE ULCER

It is not always a simple matter to determine the status of activity of an ulcer, if one depends on the symptoms alone. It is necessary to visualize the ulcer niche or other signs in the duodenal bulb, such as hyperirritability, sensitiveness or tenderness on palpation, spasticity or edema and fragmentation. Besides these observations, the presence of occult blood in the stools is of paramount importance. In this study the activity of the ulcer was based on the roentgen observations. Of the 480 cases of duodenal ulcers observed during the prewar period, 230 were active; of the 674 cases in the war period, 400 were considered to be active. These statistics revealed an increase in the incidence of activity during the war period.

Ulcer Niche.—The demonstration of the niche defect in the duodenal bulb is pathognomonic of an active ulceration. It is necessary to reemphasize that the niche is not always observed, even in active ulcerations. In the 1,154 cases of duodenal ulcer, 418 showed a demonstrable niche defect. In the prewar five year period, of 480 cases there were 160 with ulcer niches. Of the 674 cases in the second five year period 258 revealed an ulcer niche defect. It was assumed that during the war period the incidence of activity of the ulcer as indicated by the demonstration of an ulcer niche had increased. A comparison of the statistics revealed a slight increase in the incidence of the ulcer niche defect in the second five year group.

The cases involving an ulcer niche were also studied according to sex, to determine whether niches are more common in females. It is noteworthy that there was a slight increase in the finding of an ulcer niche in females in the second five year group of cases. Table 5 shows the relative incidence in both series.

Hemorrhage.—Massive hematemesis is not very common in duodenal ulcer. In this study a comparison was made of the number of cases of hemorrhage occurring in each five year period. In the 1,154 cases of duodenal ulcer, there were 41 cases of massive hematemesis. In the 480 prewar cases, there were 15, while in the 674 cases of the second five year period it was noted in 26 cases. A comparative study of the two groups of cases revealed little statistical change. There appeared to be a slightly greater incidence of hematemesis in females during the war period.

Black Stools.—The presence of black stools associated with peptic ulcer usually indicates a bleeding ulcer. It was difficult to ascertain the true incidence of tarry stools, because many patients do not observe their stools at defecation. The cases charted in table 5 are those with the recognized passage of black stools. It was of interest to note whether the incidence of black stools increased during the war period. In the 480 prewar cases of duodenal ulcer black stools were observed in 21, while in the 674 cases of duodenal ulcer in the war and postwar period it was observed thirty times.

Obstruction.—Obstruction is encountered in duodenal ulcer as a result of secondary involvement of the pylorus, edema or stricture, or pronounced contracture of the duodenum caused by cicatricial changes. In the 1,154 cases, there were 23 cases of mechanical obstruction. In the prewar group, there were 10 cases; in the wartime cases it occurred thirteen times. It is obvious that there was not any increase in the number of cases of obstruction during the war period.

TABLE 5.—*Signs and Symptoms*

	Male		Female		Total	
	Group 1	Group 2	Group 1	Group 2	Group 1	Group 2
Niches	135	198	25	60	160	258
Active ulcers	189	316	41	84	230	400
Pain	22	115	33	38	55	153
Pain—food relation	183	308	45	59	228	367
Vomiting	56	101	13	18	69	119
Hematemesis	13	16	2	10	15	26
Tarry stools (excluding tarry stools in hematemesis)	18	22	3	8	21	30
Diarrhea	22	48	6	11	28	59
Irritable, spastic colon	119	170	25	41	144	220
Pyloric obstruction	9	13	1	0	10	13

Perforations.—In the entire series of 1,154 cases of duodenal ulcer, only 10 postoperative cases were observed, occurring about equally in both five year periods.

Pain.—Pain in relation to food is one of the most characteristic symptoms of duodenal ulceration. Often there is pain without relation to food. However, pain is not always present in duodenal ulcers. Often there is only mild epigastric distress. In this series of 1,154 cases, 703 presented a history of pain; of these 595 gave the characteristic relation of pain and food.

Vomiting.—Vomiting in duodenal ulcers occurs in over 10 per cent of cases. It is often the first sign of acute onset of ulcer. It frequently occurs as a result of spasm or other pyloric involvement. Vomiting occurred in 186 of the 1,154 cases. In the 480 cases comprising the first five year period it occurred in 69; in the second five year group of 674 cases there were 119 cases of vomiting. A comparison of the two groups revealed a higher incidence of vomiting in the second five year period. This increase is probably due to the greater number of acute cases which occurred during the war.

Diarrhea and Irritable Colon.—Diarrhea, loose bowels or frequent bowel movements are commonly associated with duodenal ulcer. This condition is due to a hyperirritability and hypermotility of the entire gastrointestinal tract. In the 1,154 cases of duodenal ulcer, there were 87 cases of diarrhea, 28 cases occurring in the first five year and 59 in the second five year period. The higher incidence favored the second five year group.

An irritable colon is one of the most common roentgen findings associated with duodenal ulceration. Of the 1,154 cases, 364 cases of spastic or irritable colons were observed. In the prewar series there were 144 cases; during the war period 220 cases. A comparison of the two series slightly favored the war period.

SUMMARY

A comparative statistical study of duodenal ulceration in the civilian population was made of two five year periods, the prewar period from 1937 to 1941, and the period during the war, 1942 to 1946, to determine the effect of the war on duodenal ulceration. The incidence of duodenal ulcer among patients with digestive disturbances in a ten year period was found to be 16 per cent.

This study revealed the following information: 1. A rising trend in the incidence of duodenal ulcer during and immediately after the war amounted to about 4 per cent. 2. The comparison of the age and sex incidence in duodenal ulcers between the prewar and the war period showed no significant statistical change. 3. There was a slight increase in the incidence of cases of less than one year duration in the second five year period. 4. According to the objective roentgen findings for the determination of the activity of the ulcer, there seemed to be an increase in the percentage in the second five year study. 5. There was slight increase in the number of ulcer niches observed roentgenologically in the wartime cases. A slight increase was noted in the number of niches occurring in females in the war group. 6. There was a higher incidence of first recurrences and an increase in the incidence of "acute" ulcers during the war period. 7. In many instances the severity of symptoms seemed to be more pronounced during the war period, because of the increased number of acute ulcers. 8. The complications, obstruction and hemorrhage were not statistically different in the two groups of cases. There was a greater incidence of hematemesis in females during the war period.

ONSET OF PEPTIC ULCER IN THE AGED

HENRY A. RAFSKY, M.D.
MICHAEL WEINGARTEN, M.D.
and
CHARLES I. KRIEGER, M.D.
New York

In a previous report of 408 cases of bleeding peptic ulcer,[1] it was observed that 56 or 13.7 per cent were in patients over the age of 60 years. A review of the 56 cases revealed that in 25 of them the first symptoms of ulcer occurred after the fifth decade. A recent study of the gastric secretory response in the aged[2] showed that 12.7 per cent of persons over the age of 65 had hyperchlorhydria. In view of these observations, it was thought of interest to review a series of consecutive hospital admissions for peptic ulcer to determine the incidence of the onset of symptoms in patients over 60 years of age and the clinical course of peptic ulcer in this group.

CLINICAL STUDY

This study is based on a series of 1,800 successive admissions for peptic ulcer to two hospitals from 1941 to 1947. Three hundred and seventy-eight patients or 22.2 per cent were 60 years of age or older on admission. In 106 cases the first symptoms of ulcer occurred after the patients had reached the age of 60 years. After a careful scrutiny of the histories there was some doubt in 25 as to whether there had been any evidence or complaint referable to the ulcer prior to the age of 60. These cases were excluded from this study, leaving 81, or 4.5 per cent of 1,800 patients, in whom the history definitely indicated that the onset of the ulcer symptoms occurred after the fifth decade.

TABLE 1.—*Eighty-One Cases of Peptic Ulcer: Onset After Sixty Years of Age*

Age, Years	Location of Ulcer and Sex Distribution						Total
	Gastric		Duodenal		Both Gastric and Duodenal		
	M	F	M	F	M	F	
60-69	13	7	19	4	4	..	47
70-79	7	5	14	5	2	..	33
Over 80	..	..	1	..	..	..	1
Total	20	12	34	9	6	..	81

The age range of the patients in the 81 cases which form the basis of this study was from 60 to 81 years. Forty-seven patients were between 60 and 69 years, 33 were between 70 and 79 years and 1 patient was 81 years of age. Sixty patients were men and 21 were women. Thirty-two had a gastric ulcer (20 men and 12 women). Forty-three had a duodenal ulcer (34 men and 9 women). Six patients had both gastric and duodenal ulcers (table 1).

Clinical Aspects on Admission.—Pain was the chief complaint in 29 cases of uncomplicated ulcer; nonobstructive vomiting was present in 4 cases; 1 patient's

[2] Rafsky, H. A., and Weingarten, M.: Gastric Secretory Response in the Aged, Gastroenterology **8**: 348-352 (March) 1947.

only symptom was loss of weight. Three patients were admitted with evidence of hemorrhage and perforation. Twenty-eight patients were admitted for bleeding, 1 of whom also had a mild obstruction. Six patients had a perforated ulcer. In 2 additional cases, perforation of the ulcer occurred after the patient had been admitted for other diseases, 1 for coronary thrombosis and the other for urinary retention. Vomiting due to pyloric obstruction featured the onset in 8 patients. Forty-seven, or 58 per cent of the 81 cases, presented complications of ulcer on admission (table 2).

Gastric Analysis.—A gastric analysis employing an alcohol or Ewald test meal was performed in 40 cases. The results have been listed in table 3. It is of interest to note that hyperchlorhydria was found in 22 of the 40 patients who had a gastric analysis.

DIAGNOSIS.

In patients with a short history of gastric complaints in the advanced age group, the problem of differentiating a benign ulcerating lesion of the stomach from a malignant one often presented difficulties. The criteria employed in arriving at a definite diagnosis were the physical findings, gastric analysis, the clinical course, periodic roentgen examinations, gastroscopic examination whenever possible, disappearance of occult blood from the stools and operative and pathologic diagnoses.

In view of the complicating diseases present in many of the older patients, gastroscopy was not always feasible. This examination was performed in 13 cases. In 8 cases of gastric ulcer there was agreement between the roentgenologic and gastroscopic opinions. In 2 cases of duodenal ulcer the endoscopic examination of the stomach did not reveal any pathologic changes. In 1 case of gastric ulcer the lesion was seen on roentgen examination but not by the gastroscopist. In 1 patient, a duodenal ulcer with a crater was found roentgenologically, and gastroscopically an additional gastric ulcer of the posterior wall was observed. In another case both the roentgen and the endoscopic examinations pointed to a probable malignant growth of the lesser curvature; at operation a benign ulcer was found.

In an aged person, the differentiation between an acute episode due to coronary artery disease or to a peptic ulcer, or to the coincidence of both entities, may be difficult. This was illustrated by the following case:

M. H., a man aged 71 years, who gave a four year history of slight pyrosis, was admitted on Dec. 24, 1945, with complaints of epigastric pain radiating to the precordial region and weakness for eight days. Coronary precautions were taken after an electrocardiogram showed evidence of myocardial infarction. On Jan. 8, 1946, a roentgen examination showed an irregular pylorus and a spastic and irregular bulb. On January 16 the epigastric pain became severe, occult blood was noted in the stool and a flat roentgenogram showed free air under the diaphragm. At operation, a perforated gastric ulcer was found.

That the so-called "ulcer diathesis" may be observed in a person past 60 years of age was illustrated by the following case:

J. S., a man aged 68 years with a three year history of epigastric pain, was first admitted in April 1939, with clinical evidence of a perforated ulcer. The roentgen examination showed no air under the diaphragm, but at operation a perforated prepyloric ulcer was found and sutured. In December 1944, at the age of 73, he was readmitted with complaints of epigastric pain for one week and vomiting and hematemesis for two weeks. A roentgen study revealed a duodenal ulcer. He improved on medical therapy. In August 1945, he was again admitted, complaining of dysphagia and vomiting immediately after meals. A roentgenogram showed a funnel-shaped narrowing of the lower half of the esophagus. Esophagoscopy revealed an inflammatory lesion, a biopsy of which, after dilatation, was reported as showing an inflammatory ulcerating lesion of the esophagus.

Elderly patients without previous gastric complaints may have a perforation of an ulcer during the course of another illness, as illustrated by the following case:

A. S., a man aged 63 years, was admitted in May 1946 with acute urinary retention due to a hypertrophied prostate. He had no previous history of dyspepsia. While an intravenous pyelogram was being done, he went into shock. A roentgenogram showed free air under the diaphragm. At operation a perforated prepyloric ulcer was found.

Complicating Diseases.—In many of the patients, other pathologic conditions accompanied the peptic ulcer. Diverticulum of the esophagus was present in 1 patient, peptic ulcer of the esophagus in 1, hiatus hernia in 8, gallbladder disease in 7, Echinococcus cyst of the liver in 1 and diverticulosis and diverticulitis of the colon in 4. Arteriosclerotic heart disease was present in 22 patients, bronchial asthma in 1 and thrombophlebitis of the legs in 2. Diabetes was encountered in 2 patients, syphilis in 2, Paget's disease in 1 and diseases of the prostate gland and bladder in 6. Another patient with an obstructive ulcer had been operated on for carcinoma of the sigmoid eighteen months prior to his admission for ulcer treatment.

TREATMENT

Medical Treatment.—The uncomplicated ulcer in aged patients whose symptoms have their onset after 60 does not as a rule present any special therapeutic problem. However, certain precautions should be observed. The use of atropine or belladonna even in therapeutic doses may precipitate acute glaucoma in older patients. Soluble alkalis should never be employed in patients with impaired renal function, which is often encountered in elderly people. The alumin hydroxide preparations are preferable. The addition of magnesium trisilicate to aluminum hydroxide gel may obviate the occurrence of fecal impaction sometimes observed in old persons when aluminum hydroxide alone is employed.

The serious complication of hemorrhage appears to be more frequent in patients over 60 years of age. The objectives in the treatment of a bleeding ulcer in an elderly patient are the same as in a younger person, namely, to aid in the arrest of bleeding, overcome shock, dehydration and anemia, and prevent recurrence of hemorrhage. It is our experience that persistence with medical treatment and the liberal use of citrated blood transfusions are more often rewarded by the survival of the patient than is surgical treatment. Slow intravenous administration of isotonic solution of sodium chloride and dextrose and citrated transfusions should be used freely to combat anemia and shock without fear that any elevation of blood pressure which may result from these therapeutic measures will have a deleterious effect.

In elderly patients with impaired renal function, the occurrence of extrarenal azotemia adds to the danger of hemorrhage, and persistently high levels of nonprotein nitrogen indicate a bad prognosis. To combat this, fluids must be administered. In doing so, care must be observed to avoid overloading the heart and pulmonary edema. In addition to administering all intravenous fluids slowly, a good guide is to restrict the parenteral intake of fluid to about 3 per cent of the body weight in twenty-four hours.

The Meulengracht regimen in our opinion should not be used in the treatment of hemorrhage in elderly patients with ulcer. We have observed recurrence of bleeding, severe pain and perforation during the course of such treatment. The dietetic regimen which was employed has been outlined previously [1] and has been referred to as the "combined method." It consists of withholding all oral feedings and supplying fluids and vitamins parenterally until bleeding has ceased. If small feedings are then well tolerated, the food intake is rapidly increased.

The barbiturates are preferable to morphine as sedatives. Morphine employed during a hemorrhage may interfere with the vasomotor reactions and intensify the circulatory inadequacy.[3]

Surgical Treatment.—Nineteen of the 81 patients were operated on. In 11 a perforation was sutured. Six of these patients died. Three cases of pyloric obstruction did not yield to medical treatment. A subtotal gastric resection was performed in one, a posterior gastroenterostomy in another and a vagotomy and gastroenterostomy in the third case. All 3 patients survived. Five patients had uncomplicated ulcer refractory to medical treatment. A subtotal gastric resection was performed in 3 of them, 1 of whom died; in another patient, a posterior gastroenterostomy was done; in the fifth case, the operation could not be concluded because the patient went into shock during the procedure. She recovered and on a subsequent admission showed evidence of obstruction but refused further surgical treatment. Of the 28 cases of hemorrhage encountered in this series, 11 involved bleeding of grades 3 and 4; none of the cases of bleeding came to surgery.

Perforation of a peptic ulcer requires immediate surgical intervention, irrespective of the age of the patient. Clinical experience has shown that the mortality rate in these cases depends largely on the time which elapses between the perforation and the operation and the amount of gastric contents at the time of rupture. This holds true especially in elderly patients, who as a rule are not good surgical risks.

Pyloric obstruction due to ulcer in older patients often responds to medical measures. Gastric lavage, antispasmodics, a liquid and semiliquid diet were employed to determine whether the stenosis was of an inflammatory or cicatricial origin. In the latter type, surgical treatment was advised. In either case, dehydration and hypoproteinemia must be corrected and the chemical balance restored.

In those cases in which there is bleeding from an ulcer or an erosion in a hiatus hernia, phrenic crushing is sometimes performed after the cessation of hemorrhage. This procedure may prevent recurrent bleeding.[4]

In the treatment of elderly subjects it is advisable to have the period of bed rest as short as possible. Early ambulation helps to prevent pulmonary embolism.

MORTALITY

Thirteen patients, or 16 per cent of the 81, died. Of 11 patients with perforation, all of whom were operated on, 6 or 55 per cent succumbed. Of 28 patients with hemorrhage, all of whom were treated medically, 3 or 10.7 per cent died. Of 29 patients without complications of ulcer, 1 died after a subtotal resection, 1 from a carcinoma of the prostate and hemiplegia, 1 from a coronary occlusion, and 1 from pulmonary embolism secondary to thrombophlebitis of the legs. Of the 19 patients operated on, 7 died, a mortality of 36.8 per cent.

COMMENT

The increase in the number of persons over 60 years of age in the general population has led to a greater interest in all disease processes which affect them. It seems worth while to emphasize the not infrequent onset of peptic ulcer in the aged. The necessity of considering peptic ulcer and its complications in elderly persons in the differential diagnosis of abdominal complaints of relatively short duration is obvious.

Complications of ulcer seem to occur more frequently in those persons with an onset of symptoms late in life. The general incidence of hemorrhage in patients of all ages hospitalized for peptic ulcer is approximately 30 per cent. In a series reported by Keefer and McKell of aged patients with ulcer, hemorrhage was present in 31 per cent.[5] In the group of 81 cases which is the basis of this study, hemorrhage was present in 38 per cent.

None of the patients with hemorrhage uncomplicated by perforation were operated on. It is interesting to compare the mortality of 10.7 per cent in this group of bleeding ulcers in patients over 60 years of age, observed between 1941 and 1947, with that of a group of patients, over 50 years of age, treated from 1927 to

1941.[1] In the latter group there was a 16.4 per cent mortality in those patients treated by various medical regimens and a 20 per cent mortality in those treated surgically. We attribute the improvement in the survival rate in the group now being reported to the increased and unsparing use of citrated blood transfusions and intravenous infusions which serve to keep the patient alive until healing of the ulcer and cessation of bleeding can take place. Hypertension is no contraindication to the use of transfusions, when indicated, and hypertension in a patient with bleeding ulcer has little effect on the severity of the bleeding. Our present experience corroborated this previously recorded observation.[6] Secondary hemorrhage in elderly persons does not necessarily constitute a definite indication for surgical intervention. We have seen elderly patients who had severe secondary hemorrhage and who survived with medical treatment. Any routine employment of surgery in the older group of patients with bleeding ulcer would probably result in a higher mortality than that which occurs with persistence in medical measures. However, if a patient has a hemorrhage which is so rapid and profuse as to produce a state of impending shock, massive transfusions and surgery should be employed immediately.

It has been stated that perforation of an ulcer rarely occurs in a patient over 50 years of age.[7] In the present series, perforation occurred in 11 patients or 13.8 per cent. Some of the perforations occurred in elderly patients without any previous gastric complaints. The incidence of perforation as a complication of hemorrhage in ulcer is generally considered to be 1 per cent. In this series, 10 per cent of the patients who had a hemorrhage also had a perforation. Our experience would indicate that perforation of peptic ulcer is not uncommon in older patients.

Pyloric obstruction is another complication which is not infrequently seen in elderly patients with peptic ulcer. It may be the first indication of the presence of an ulcer. Pyloric obstruction in an older patient with a short history of gastric complaints and loss of weight presents an especially difficult diagnostic problem in differentiating a benign from a malignant lesion. Obstruction due to ulcer in an elderly patient often responds to medical treatment. In younger patients, a severe degree of organic obstruction may at times be compatible with relative comfort. Elderly persons suffering from cicatricial pyloric stenosis are much more susceptible to alkalosis, hypochloremia and azotemia. Therefore, if these patients do not respond readily to medical treatment, surgical treatment is more imperative, and should be performed after the chemical imbalance has been corrected.

SUMMARY

In a series of 1,800 successive hospital admissions for peptic ulcer, 81, or 4.5 per cent of the patients, had no symptoms referable to the ulcer prior to reaching the age of 60 years. Fifty-eight per cent of the 81 patients had complications of ulcer on admission. Hemorrhage was the chief complaint in 38 per cent of the cases. The mortality from hemorrhage in this series was 10.7 per cent. No case of bleeding was treated surgically. Liberal use of slowly administered infusions and transfusions are advocated, when necessary, in the treatment of hemorrhage due to ulcer in the aged. Hypertension is not a contraindication to these measures.

Perforation was the initial evidence of ulcer in 13.8 per cent of the cases, and the mortality of this complication was high. Pyloric obstruction due to ulcer in the aged often yields to medical treatment. Surgical treatment is imperative in those patients whose obstruction is refractory to medical therapy.

Complicating diseases play an important role in the prognosis of ulcer in elderly patients.

RESULTS OF VAGUS NERVE RESECTIONS IN TREATMENT OF PEPTIC ULCER

An Anatomic, Physiologic and Clinical Study

WALTMAN WALTERS, M.D.
HAROLD A. NEIBLING, M.D.
WILLIAM F. BRADLEY, M.D.
JOHN T. SMALL, M.D.
and
JAMES W. WILSON, M.D.
Rochester, Minn.

We have on previous occasions reported in detail our studies on the variations in the anatomy of the vagus nerves and the early results which have followed the performance of vagus nerve resections for gastroduodenal and jejunal ulceration, first in a group of 66 cases and later in a group of 83 cases which included the original 66 cases.[1]

In the second report, as well as in the first, the cases were divided into two series: (1) those (40 cases) of one of us (W.W.), in which the approach was through the abdomen in all but 1 case and (2) those (43 cases) in which the operation was performed by other surgeons at the Mayo Clinic (table 1). Nineteen of the forty-three operations were performed transthoracically.

Since the results of operation in the 83 cases have already been reported in detail we have confined ourselves in this brief report to a summary of the results, both favorable and unfavorable, in our cases (series 1), which now total 50, and in the cases of our colleagues (series 2), which now (May 1, 1947) total 68 (table 2).

SERIES 1. (OUR CASES)

In our 50 cases resection of the vagus nerves has been performed in 34 cases of duodenal ulcer, in 7 cases of gastrojejunal ulcer and in 9 cases of gastric ulcer.

From the Division of Surgery, Mayo Clinic (Dr. Walters) and the Mayo Foundation (Dr. Neibling, Fellow in Surgery; Dr. Bradley, Fellow in Medicine; Dr. Small, Fellow in Surgery, and Dr. Wilson, Fellow in Surgery).

Read in a symposium on Peptic Ulcer before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Gastro-Enterology and Proctology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

DUODENAL ULCER

First of all it must be remembered that the patients with duodenal ulcer selected for vagus nerve resections were chosen from that group of approximately 12 per cent of all patients with duodenal ulcer seen at the clinic in whom an operation of some type was thought to be necessary since nonsurgical methods had failed. This would comprise those whom we formerly would have considered suitable for partial gastrectomy. This rate of 12 per cent contrasts with that of 37.6 per cent of patients in whom operations for duodenal ulcer were performed in 1928 (table 3).

In 21.2 per cent of the patients operated on in 1928, the ulcer was small and nonobstructive and the duodenum was movable enough so that excision of the ulcer with pyloroplastic procedures was carried out. Much is made of this fact because with a decrease in the percentage of patients operated on for duodenal ulcer, most such patients now are found to have at operation large, obstructing, perforating or hemorrhagic duodenal ulcers; in such patients it would be necessary to perform an associated drainage operation of the stomach to prevent gastric retention if vagotomy were performed. Thus, in our series of 50 cases, in only 19 was it thought advisable to do a vagus nerve resection without some other simultaneous operation of the stomach, such as either a drainage operation to prevent postoperative gastric stasis or excision of a gastric ulcerating lesion; likewise, in our colleagues' series, in 30 of 68 cases vagotomy was done without other procedure on the stomach.

§ Colp, R.: Unpublished data.

In discussing the results of the operation we can accept the fact that a complete vagus nerve resection relieves the pain of ulcer and that objectively there is a decided reduction of gastric acidity to an achlorhydric state in more than 50 per cent of cases. These results, however, are both secured at the expense of tonicity of the stomach: dilatation of the stomach occurs which, as a result of the retention of food within it, may produce troublesome symptoms, such as frequent belching of foul gas, a feeling of epigastric fulness and occasionally nausea, vomiting and diarrhea. It would appear that the results of vagotomy should be best in those cases of nonobstructing duodenal ulcer, but in our experience relatively few of the patients with duodenal ulcer who are operated on at the clinic have nonobstructing ulcers.

Vagotomy Only.—In only 10 [2] of the 34 patients with duodenal ulcers operated on by us has vagotomy been done without other simultaneous gastric operations (table 4). Six of these 10 patients had complete relief of symptoms, some up to a year after operation. Despite this, roentgenologic examination on dismissal showed a duodenal ulcer without crater in 4 patients, 2 of whom gave a positive reaction to the insulin test (table 5). An atonic dilated stomach in 3 patients was present when they were dismissed from the clinic. Gastric acidity was reduced in 5 of the 6 cases; achlorhydria developed in 2 of these 5 patients despite a positive reaction to the insulin test in 1 of the 2. The sixth patient had no preoperative studies of gastric acidity, and postoperatively he gave a positive reaction to the insulin test.

TABLE 2.—*Gastric Neurectomy: All Cases to May 1, 1947*

		Operation Performed for

Total	118	71	37	10

Three of the 10 patients had no distress from the ulcer but did have fulness and bloating, and 1 of the 3 was having diarrhea six months postoperatively. In 2 of these 3 patients achlorhydria occurred and the reaction to the insulin test was negative. The third patient had no reduction in gastric acidity and gave a positive reaction to the insulin test; this patient early had fulness and bloating. When last heard from seven months postoperatively he had no distress and had gained 10 pounds (4.5 Kg.).

One of the 10 patients died one hour postoperatively of coronary insufficiency.

Vagotomy Associated with Other Gastric Operations.—Sixteen of 22 patients who underwent vagotomy associated with gastroenterostomy had good results despite the fact that 7 had some fulness after meals in the early postoperative period and 1 of the 7 had a

---

2. Three of the 10 had associated cholecystectomy at the time of gastric neurectomy. One of these also underwent appendectomy. In a fourth case biopsy of a small area of mesentery revealed fat necrosis.

physiologic obstruction for twenty-six days which necessitated jejunojejunostomy. This latter patient had a reduction in gastric acidity but no insulin tests were made. He was in excellent health eight months postoperatively. Of the 15 other patients, 7 had evidence of atonicity on roentgenologic examination. Three of these showed evidence of gastroenteric stomas which did not function well although they were open. Five of the 15 patients had achlorhydria, and the others had reduced gastric acidity. Nine of the 15 gave a negative reaction to the insulin test and 1 gave a positive reaction.

		2	3 to 4 weeks	No distress (jejunitis by roentgenogram)	Reduced	Negative
Gastric......................	1	2	6	Ulcer distress	Temporary achlorhydria	Negative

* Patients with persistence or recurrence of ulcer. † Preoperative acids not available.

Four patients had mild symptoms of diarrhea with bowels moving loosely two to four times a day. In 3 of these relative achlorhydria developed and the reaction to the insulin test was negative. One had no postoperative studies of gastric acidity.

Two patients had early retention of gastric contents and later had bad results. One of these has continued to have distress from ulcer with gas and fulness. No insulin test was done in this case and the patient did not have a reduction of gastric acidity; apparently not all of the nerve fibers were resected. The second patient had such a severe postoperative ileus that mechanical obstruction was suspected, but this was not found at reexploration seven days after vagotomy and gastroenterostomy. This patient died nine months postoperatively, at home, after being operated on for volvulus of the terminal ileum and mesenteric thrombosis.

Two patients had other gastric operations, one a partial gastric resection and the other an excision of ulcer and pyloroplasty. Both of these had relief of the distress from ulcer; the results of the insulin test were negative and there was achlorhydria.

GASTROJEJUNAL ULCER

There were 7 cases of gastrojejunal or postoperative gastroduodenal ulceration. All of these patients gave histories of intractable pain of long duration. Five of these patients had had gastroenterostomy. One patient had had a Devine exclusion type of partial gastrectomy. The remaining one had had a Billroth I type of gastric resection.

Five patients of the group, in addition to vagotomy, underwent removal of the gastroenteric stoma and the jejunal ulcer; in 2 of these pyloroplasty was also done because of the stenosis produced by the duodenal ulcer which had healed after gastroenterostomy. In 1 patient an anterior Polya-Balfour gastric resection was done, in addition to removal of the gastroenteric stoma and the ulcer.

In 4 of the 7 cases results were excellent, with relief of pain and with no complaints of fulness, bloating, nausea or diarrhea. The other 3 patients had what might be considered satisfactory results. One of these patients complained of a short spell of anorexia and loss of weight after being perfectly well for six weeks postoperatively. Two had minor complaints of fulness after meals which had lasted for several weeks in one and was still present at the end of six months in the other.

Studies of gastric acidity in these 7 patients revealed a mean reduction from 30 units of free hydrochloric acid preoperatively to 13.5 units postoperatively (Töpfer's method); 4 patients of the 7 had achlorhydria postoperatively and are considered in obtaining this average. Insulin tests were done in 6 with negative results.

When the severity and prolonged nature of the illness of these patients are considered, the results of vagotomy with removal of the gastrojejunal ulceration and the gastroenteric stoma appeared to be satisfactory as far as early results are concerned. It must be remembered, however, that equally good results occur in 50 per cent of cases when removal of the gastrojejunal ulcer and the gastroenteric stoma is done without vagotomy.

Disturbances of motility appeared in 2 patients in this group and later complications such as recurring duodenal ulceration were not encountered.

GASTRIC ULCER

In spite of the fact that the operation of subtotal gastrectomy in the treatment of chronic gastric ulcer has given excellent results with a very low mortality, we felt it advisable to perform vagus nerve resection in a small series of patients with different-sized gastric ulcers in order to determine the results of the operation and to compare them with the results in patients who had undergone partial gastrectomy for ulcer.

Nine patients were chosen for the procedure. In 4 of these patients the gastric ulcers were relatively large, the diameter varying from 1.5 to 5 cm. In addition to the performance of a vagus nerve resection, openings were made in the stomach in 4 cases, and after gross examination the ulcers in 2 cases were removed for microscopic examination. In the remaining 5 cases the ulcers, although chronic in type and small, were neither removed nor subjected to biopsy. Relief of the pain from the ulcer was obtained in 7 of the 9 patients despite the fact that 3 of the 7 had positive reactions to the insulin test; 2 patients did not have achlorhydria but both had reduced acidity and 1 had a positive reaction to the insulin test.

In 2 patients the ulcer persisted, as evidenced by the roentgenographic findings, and produced pain. Both of these patients gave repeatedly negative reactions to the insulin test, indicating that all branches of the vagi had been cut. One of these patients had a course of intensive (six months) medical management after complete vagotomy without effect on the ulcer. Partial gastrectomy with removal of a large benign perforating gastric ulcer 2.5 cm. in diameter was done six months after vagotomy. In this case, one month after operation roentgenologic examination of the stomach gave negative results; an adequate, free anastomosis was present and there was no gastric distress. The other patient, reexamined two and one-half months postoperatively, had a questionable area of ulceration high on the lesser curvature on roentgenologic examination. He has had occasional slight distress from ulcer, with considerable bloating and gas. In a communication seven months after operation he stated that he had vomited occasionally and that he had some diarrhea. Insulin tests on this patient have also given consistently negative results.

Motility was studied clinically, roentgenoscopically and roentgenographically. In 3 of the 9 patients no evidence of disturbance of motility was obtained by either method of study. One of these 3 patients gave a positive reaction to the insulin test. The remaining 6 patients showed evidence of an atonic dilated stomach, and it was in this group that the patients complained of fulness, bloating and belching of foul-smelling gas. Two of the patients also had some vomiting and diarrhea. One of the patients in whom these symptoms continued for seven months subsequent to operation was started on a course of carbaminoyl-beta-methylcholine chloride ("urecholine") as recommended by Machella, Hodges and Lorber,[3] with roentgenographic evidence of immediate improvement of gastric motility but with little evidence of clinical benefit.

In this group of 9 patients there was a decided reduction of gastric acidity from a mean preoperative value of 38 units of free hydrochloric acid to 5.1 units postoperatively. In 6 of the patients achlorhydria was obtained. Of the 3 patients in whom achlorhydria was not obtained, 2 gave a negative reaction to the insulin test and 1 reacted positively. Two patients who had no free fasting hydrochloric acid two weeks after operation were found to have a return of small amounts of free hydrochloric acid when observed one month and three months later, respectively.

In general, in the group of 9 patients with gastric ulcer 7 obtained relief of pain. All had reduction of gastric acidity but 3 had prolonged disturbances of motility. One ulcer failed to heal and one ulcer recurred despite apparent complete section of the vagus nerves, as demonstrated by clinical and laboratory tests, including the insulin test.

SUMMARY OF RESULTS IN SERIES 1

Vagotomy Alone.—In our series of 50 cases to date vagotomy alone was done without other procedure in 10 patients with duodenal ulcer, in 2 with gastrojejunal ulcer and in 5 with gastric ulcer. All of these patients obtained relief of the pain caused by ulcer. Three of the 10 patients with duodenal ulcer and 1 of the 5 with gastric ulcer had disturbances of motility. One patient with duodenal ulcer and 1 with gastric ulcer each gave a positive reaction to one insulin test postoperatively, and neither had a reduction of gastric acidity. Four of the patients with duodenal ulcer were reported at dismissal (approximately two and a half to three weeks after operation) as still having visible ulcers on roentgenologic examination. Two of these patients gave a positive reaction to the insulin test.

Vagotomy with Other Gastric Operation.—Vagotomy with a simultaneous gastric operation was done in 24 patients with duodenal ulcer, in 5 with gastrojejunal ulcer and in 4 with gastric ulcer. In 23 of the 24 patients with duodenal ulcer, in all 5 of the patients with gastrojejunal ulcer and in 2 of the 4 patients with gastric ulcer, relief of distress from the ulcer was obtained. Ulceration recurred in 1 patient with gastric ulcer in whom subtotal gastrectomy was necessary six months later, and in another the gastric ulcer failed to heal. Both had pronounced reductions of gastric acidity and repeatedly negative reactions to the insulin test after vagotomy. Six of the 24 patients with duodenal ulcer who had associated gastroenterostomy, 2 of 5 patients with gastrojejunal ulcer and 3 of 4 patients with gastric ulcer all had moderate to marked disturbances of motility. Of these, 1 of the patients with duodenal ulcer who reacted negatively to the insulin test and 1 patient with gastrojejunal ulcer who reacted positively to the insulin test had no reduction in gastric acidity.

The total incidence and the incidence by type of lesion for motility disturbances are given in tables 6 and 7 respectively.

SERIES 2 (COLLEAGUES' CASES)

The data presented in series 2 were obtained by a review of the records of all the other patients operated on at the Mayo Clinic over the same period as those personally operated on and studied by one of us (W. W., series 1). They are presented in order to complete the record of the results of vagotomy in the treatment of duodenal, gastrojejunal and gastric ulcer at the Mayo Clinic until May 1, 1947 (table 8). As both are factual reports no conclusions will be drawn.

DUODENAL ULCER

Vagotomy Only.—In 8 cases of duodenal ulcer no other operation was performed; 5 of these were done transthoracically and 3 abdominally.

Transthoracic Approach: Four of the 8 patients who underwent vagotomy only had good results although 2 had some trouble immediately after operation. Both of these had retention of food and fluid which, in 1 of them, necessitated gastroenterostomy for obstructive manifestations two months after vagotomy. This patient had a reduction of acidity and gave a negative reaction to the insulin test. The other patient had a severe episode of pain fourteen days postoperatively and was thought possibly to have an acute perforation of the duodenal ulcer. The pain gradually subsided. He had also obtained achlorhydria from the operation. All 4 patients, some until eleven months after operation, reported that they were feeling well. One patient had early retention with belching and fulness. He had a reduction in gastric acidity, but no insulin test was done. Eight months after operation there was no distress from ulcer but the patient complained of gas and occasional episodes of diarrhea.

Abdominal Approach: One of the 3 patients who underwent vagotomy abdominally was well at dismissal and had had a reduction of gastric acidity. Another patient had retention early postoperatively with intermittent periods of vomiting and diarrhea three months postoperatively. Roentgenologic examination at that time revealed that the duodenal ulcer was still present. The patient had a reduction of acidity but no insulin tests were made. Seven months postoperatively he was still having slight pain after eating, some gas, fulness and bloating. The third patient died suddenly on the fourth postoperative day and, although no necropsy was performed, death was thought to be due to an embolus.

Vagotomy and Associated Gastric Operations for Duodenal Ulcer.—Twenty-five patients with duodenal ulcer underwent vagotomy and gastroenterostomy. Twenty-four of these had relief of the symptoms of ulcer. Eighteen of these 24 patients had no disturbances of motility. Thirteen of the 18 had reduction of gastric acidity, 4 obtaining achlorhydria. Only five insulin tests were made and the reaction in one of these was positive. Six patients had disturbances of motility characterized by epigastric fulness, nausea or diarrhea. Three of these had postoperative studies of acidity and in all the acidity was reduced. No insulin tests were made.

One patient with pronounced postoperative gastric retention and hypoproteinemia died on the fourteenth postoperative day. At necropsy an unexpected perforated duodenal ulcer with subdiaphragmatic abscess was found.

Vagotomy and Pyloroplasty.—Four patients underwent pyloroplasty in addition to vagotomy. All of these obtained relief of distress from ulcer. Two had disturbances of motility of consequence. One of these 2 patients was still complaining of fulness, bloating and diarrhea six months postoperatively; he had lost 10 pounds. The other patient early had similar symptoms which lasted about ten months. For the past six months this patient has been free of such symptoms. Both of these patients had a reduction of gastric acidity, but no insulin tests were made.

GASTROJEJUNAL ULCER

There were 30 cases of gastrojejunal ulcer in which vagotomy was done. In 3 of these the operation was performed too recently to permit of evaluation. Of the remaining 27 cases, in 15 the operations were done transthoracically and in 12 abdominally.

Transthoracic Approach.—Nine of 15 patients had good results from vagotomy with absence of all symptoms of ulcer. Seven had had gastric resection and 2 had had gastroenterostomy previously. Three of the patients previously subjected to gastric resection had absence of symptoms of ulcer but had mild disturbances of motility. One of these had transient abdominal distention for a few weeks while the other 2 complained of diarrhea which lasted a few weeks and nine months, respectively.

Three patients had unsatisfactory results with recurrence of the symptoms of ulcer. One of these, who had had three previous gastric resections, suffered from a severe gastric hemorrhage a year after vagotomy. In the preceding year since vagotomy he had been in better health than in the previous ten years, with only mild complaints of generalized abdominal discomfort and constipation which he ascribed to his old adhesions. The second patient who had had gastric resection previously showed persistence of the ulcer on roentgenologic examination one month after operation and experienced symptoms of ulcer two months after vagotomy; this patient responded well to medical treatment. The third patient had had repeated exsanguinating hemorrhages after gastroenterostomy and continued to bleed for six months after vagotomy performed elsewhere. Resection was done at the clinic and a large stomal ulcer was found. In only the first of these 3 patients did achlorhydria develop after vagotomy and in only the third patient was an insulin test done which gave positive results. Therefore vagotomy was suspected of being incomplete in 2 patients and inadequate in the third.

One patient dismissed with no complaints had no drop in acidity and gave a positive reaction to the insulin test. Four patients had sufficient postoperative pleural effusion to require aspiration. Three of 8 patients checked roentgenologically after operation showed a low grade ileus of the upper part of the small bowel, in 1 of whom the motility was normal three months later. In 3 cases the ulcer had healed several weeks after operation and in 1 the ulcer had decreased in size.

Abdominal Approach.—In 7 patients the existing anastomosis was not disturbed; 4 of these had had previous gastroenterostomy and 3, gastric resection. Three had obtained good results clinically when dismissed, though in 1 the value for total acidity was still 100 units and for free acidity 80 units. No insulin test was done in the latter case. Three still complained of minor degrees of fulness and diarrhea several months after operation; 1 of these had a malfunctioning enteric stoma with possible persistence of the ulcer, as evidenced on roentgenologic examination several weeks after operation. The remaining patient noticed gas and dizziness when hungry which was relieved by frequent small meals.

One patient underwent disconnection of the enteric stoma as well as vagotomy. He had no drop in gastric acidity, and the insulin test gave positive results. He suffered from retention and vomiting for a month and was still belching foul gas and vomiting occasionally four months later.

One patient underwent disconnection of the enteric stoma and pyloroplasty with good results. One patient had the gastroenteric stoma disconnected and gastroduodenostomy done. He had occasional ulcer distress and fulness but was in good health otherwise. Two patients with gastrojejunocolic fistula had good early results after disconnection of the enteric stoma, closure of the fistula and reestablishment of the enteric stoma, in addition to vagotomy. One died at home three and a half months postoperatively from a coronary occlusion as reported by his home physician.

Table 8.—*Results of Vagotomy Three Weeks to Seventeen Months After Operation (Series 2)*

		Mean Free Acids		Roentgenogram Two and a Half Weeks After Operation									
Ulcer	Cases	Pre-operative	Post-operative	Normal Motility	Atony	Ulcer Present	Ulcer Distress	Fulness	Gas	Vomiting	Diarrhea	Relief of Symptoms	Deaths

§ Cerebral hemorrhage on thirteenth postoperative day.
¶ Negative insulin reaction.
‖ Positive insulin reaction.
Coronary occlusion three months after operation; gastrojejunocolic fistula.

GASTRIC ULCER

Only 1 patient with gastric ulcer, which was located in the pyloric ring, was studied in series 2. The ulcer was excised and pyloroplasty was done simultaneously. The patient obtained early relief of symptoms and a reduction in acidity. No insulin tes[illegible]postoperative roentgenogram was made.

RESULTS OF SURGICAL TREATMENT FOR GASTRIC ULCER

SAMUEL F. MARSHALL, M.D.
and
MARK L. WELCH, M.D.*
Boston

Gastric ulcer presents a serious problem in its treatment because of possible malignant degenerative changes arising in a benign ulcer and especially because of the considerable percentage of diagnostic errors made in distinguishing between benign and malignant ulceration of the stomach. We believe it will be of value to discuss these serious aspects of the problem and to present the results of experiences at the Lahey Clinic with the surgical treatment of gastric ulcer over a ten year period (1936 to 1945 inclusive). From this study an attempt will be made to draw some conclusions regarding the management of peptic ulcer arising in the stomach.

This study is in order because in the past we have advised a more or less conservative approach; that is, employment of a medical regimen rather than a surgical procedure in the treatment of the majority of patients with gastric ulcer. Surgical treatment was used only in those cases in which the ulcer failed to heal with medical measures or in those in which there was a reasonable suspicion of malignancy after a period of trial medical management.

It is now our considered opinion that a more positive and aggressive attitude should be accepted in the treatment of gastric ulcer and that this treatment is and should be primarily surgical. Possibly a few patients with acute gastric ulcers should be treated medically and even these should not be observed over a long period unless healing is demonstrated to occur promptly under treatment and is maintained. We wish to state in the beginning that this opinion regarding surgical treatment of all patients with gastric ulcer represents the view of the surgical division and that our division of gastroenterology is not in complete accord with this policy. Furthermore, it is emphasized that all patients with gastric ulcers should be hospitalized during this period of observation and medical treatment and, in the event of nonhealing or if the ulcer defect does not completely disappear, should have immediate operative intervention while they are still confined to the hospital. The treatment of patients with duodenal ulcer presents in many ways such a different problem and the indications for surgical intervention are so well known that one cannot compare in each particular its treatment with the problem of treatment of gastric ulcer. By way of contrast, the treatment of duodenal ulcer is generally recognized to be primarily medical in the majority of cases. Only those patients with presenting complications such as hemorrhage, intractability, perforation and obstruction require operation; in our experience about 8 per cent of duodenal ulcers have required surgical intervention. It is essentially correct to state that the major problem in the treatment of gastric ulcer is so fundamentally that of early detection of gastric carcinoma as well as relieving ulcer distress that the treatment of gastric ulceration must be approached from an entirely different aspect from that of the treatment of duodenal ulcer.

INCIDENCE OF CANCER

Over a period of ten years (1936 to 1945 inclusive), in those cases in which a preoperative diagnosis of benign gastric ulcer has been made, partial resection was carried out on 131 patients. The pathologic study of the removed lesions disclosed carcinoma in 26 of the 131 cases, a diagnostic error of 19.8 per cent in the cases in which operations were done. During this same ten year period, approximately 8,000 patients with peptic ulcer were treated. Of this number 800 had gastric ulcers, a proportion of one gastric ulcer to nine duodenal ulcers; in other words, gastric ulcer occurs much less commonly than duodenal ulcer. Eusterman and Balfour [1] have also stated that in their experience duodenal ulcer is ten times more frequent than gastric ulcer. In the entire group of 800 patients with gastric ulcer treated medically and surgically, there were 26 proved malignant gastric ulcerations, an incidence of proved malignancy of 3.3 per cent for the entire group. This is assuming that none of the patients treated medically proved later to have cancer, a most unlikely possibility. This group of patients not operated on is at present under study in the gastroenterology department. From these data it may be seen that only 131 of 800 patients were treated surgically, a percentage of 16.4. It is only fair to state, however, that all patients in this group of 131 cases, many of whom proved to have malignant ulcers, were ultimately submitted to operation by the gastroenterologist because of failure to heal and because, therefore, gastric cancer could not definitely be ruled out. Yet it is equally pertinent to point out that 17 of this group of 26 patients had been treated one month or longer before decision to operate had finally been arrived at, definite evidence that these patients had been considered to have benign lesions. This trial period of observation over a month we now consider to be too long; decision regarding necessity of surgical intervention should be made much earlier. It would seem likely that some of this group with gastric ulcers in which the treatment was medical must have proved subsequently to have cancer, and only a careful and accurate follow-up of these medically treated patients could disprove this possibility. It is apparent that the problem of diagnosis and treatment of gastric ulcer is a serious one and demands a radically different approach in the treatment and care of these patients.

Allen and Welch [2] reported a similar experience in a study of gastric ulcer. In a group of 277 patients treated medically and surgically, 39, or 14 per cent, were proved to have cancer. Moreover, in a group of 69 patients of his series treated by resection, 30 (43 per cent) were proved histologically to have cancer. Judd and Priestley [3] stated that in their experience the error in preoperative diagnosis of gastric ulcer in differentiating it from gastric carcinoma is approximately 10 per cent.

*Now residing in Dallas, Texas.

From the Department of Surgery, The Lahey Clinic.

Read in a symposium on Peptic Ulcer before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Gastro-Enterology and Proctology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947

1. Eusterman, G. B., and Balfour, D. C.: The Stomach and Duodenum, Philadelphia, W. B. Saunders Company, 1935, p. 259.
2. Allen, A. W., and Welch, C. E.: Gastric Ulcer: Significance of This Diagnosis and Its Relationship to Cancer, Ann. Surg. **114**: 498-509 (Oct.) 1941.
3. Judd, E. S., Jr., and Priestley, J. T.: Treatment of Gastric Ulcer, Surg., Gynec. & Obst. **77**: 21-25 (July) 1943.

Holmes and Hampton[4] very properly pointed out that the successful treatment of patients with cancer of the stomach by any method available at the present time depends on early diagnosis more than on any other single factor, and from roentgenologic study it may be most difficult to determine the benign or malignant character of chronic gastric ulceration. They concluded from their studies that any chronic indurated ulcerative lesion within 2.5 cm. of the pylorus should be considered to be carcinoma. They stated that this is equally true of lesions of the greater curvature and probably of most lesions in the cardiac end of the stomach.

Sproull,[5] in a careful review of the literature, found only 10 proved cases of benign chronic ulceration on the greater curvature. At the Lahey Clinic only 2 such benign ulcerations of the greater curvature have been encountered over a much longer period than this study encompasses. Consequently, we believe that no lesion of the greater curvature should ever be treated medically. It is more or less generally accepted that most benign chronic indurated ulcers occur on the lesser curvature of the stomach above the re-entrant angle, but in this location also the same diagnostic difficulty arises in deciding whether the lesion is benign or malignant.

TABLE 1.—*Malignant Ulceration*

	Cases
A. Diagnostic study and management in hospital (6 to 30 days): clinical improvement and decrease in size of ulcer—discharged; returned 4 months to 3 years later with malignant ulcer	7
B. Hospital treatment and Levine tube drainage for pyloric obstruction (3 to 10 days); operation disclosed malignancy...	3
C. Hospital treatment with clinical improvement and decrease in size of ulcer; operation; malignant	1
D. Hospital treatment but no change in size of lesion	7
E. Ambulatory treatment (6 weeks to 3 months); hospital treatment (10 to 15 days); clinical improvement but no change in lesion	2
F. Ambulatory treatment (6 weeks to 6 months): response to treatment not satisfactory; operation	3
G. Ambulatory treatment, with relief; operation for acute perforation of malignant ulcer	1
H. Hospital study—favored benign ulcer; operation because of uncertainty about malignancy	2
Malignant ulcer	26

The response to treatment for ulcer also may be misleading, since patients with malignant ulcers often do well on an ulcer regimen and the lesions appear to become smaller on roentgenologic studies, but never quite disappear. These facts are illustrated in table 1.

In this series of 131 cases of chronic gastric ulceration with the preoperative diagnosis of benign gastric ulcer in which partial resection was finally carried out, there were, as previously stated, 26 malignant lesions and 105 benign gastric ulcers, a percentage of malignant ulcers of 19.8. In none of these cases was the unqualified diagnosis of cancer made; cancer was suspected in some of these patients but all save 2 were treated medically in the hospital or as ambulatory patients. In 2 cases in which the diagnosis was benign ulceration but medical treatment was not given, operation was performed and the lesions proved to be malignant. In table 1 are listed in detail the diagnostic problems and errors. From this table it is apparent that roentgenologic examination and careful study will not definitely determine whether the lesion is malignant. It may also be noted that 9 of the 26 patients demonstrated improvement under a medical regimen and at the same time the ulcer decreased in size, as demonstrated by roentgenologic study, in spite of the fact that it was malignant.

TABLE 2.—*Ages of Patients with Malignant and with Benign Ulcers*

	Malignant Ulcer, Years	Benign Ulcer Years
Average age	51	53
Average age, men	53.7	52.2
Average age, women	42.3	57.3
Oldest patient	79 (male)	82 (female)
Youngest patient	20 (female)	30 (male)

DIFFERENTIATION BETWEEN BENIGN AND MALIGNANT LESIONS

With regard to the sex incidence, 5 patients with malignant ulcerations were women and 21 were men, a ratio of 4 men to 1 woman. In the group of 105 patients with benign ulcers, the proportion was 3 men to 1 woman—28 women to 77 men. It is well known that gastric ulcer occurs more frequently in men than in women. According to Dible,[6] 72 per cent of gastric ulcers are in men; in our benign group, 77 per cent occurred in men. In a report by Walters and Clagett[7] of 272 patients operated on for gastric ulcer, there were 220 men and 52 women, a percentage of 80.9 in men. The Mayo Clinic[1] in another report gave the proportion of men to women as 3.9 to 1.

A study of the age of patients as a determining factor in making a diagnostic distinction between carcinoma and benignity was of little value. The average age of patients with malignant ulcer was 51 and of those with benign ulcer, 53 years (table 2). Sixty-five per cent of those with malignant ulcers were in the age group of 40 to 59 years, whereas 56 per cent of patients with benign lesions fell into the same age group. Moreover, the youth of a patient is not a definite indication that the lesion is benign, as our youngest patient with malignant ulcer was 20 years of age (table 3). The duration of ulcer distress may likewise not be significant, as 1 patient, aged 79 years, with malignant gastric ulcer, had intermittent symptoms of ulcer distress while on an ulcer regimen and diet over a period of seven years.

TABLE 3.—*Age, by Decades of Patients with Malignant and with Benign Ulcers*

Age by Decades, Years	Malignant Ulcer	Benign Ulcer
20-29	1	0
30-39	2	11
40-49	7	27
50-59	10	43
60-69	5	18
70-79	1	6
Total	26	105

It is also of interest to note that gastric ulcer occurs commonly in the older age group; 83.8 per cent of benign ulcers in this series were in patients over 40 years of age, whereas in the malignant group 84.6 per cent were in patients over 40, almost identical figures. Because of this tendency of either benign or malignant ulcers to occur in persons past 40 years of age and because at this age one may be said to begin the so-called cancer age, the physician should from the onset seriously consider that gastric ulcerations may be malignant rather than benign.

Table 5.—*Size of Gastric Ulcer*

	Malignant Ulcer	Benign Ulcer
Average	2.8 cm.	1.9 cm.
Smallest	7.5 mm.	8.0 mm.
Largest	5.0 cm.	7.5 cm.
Larger than 2.5 cm	61.5%	27.0%

Gastric symptoms are likely to be similar in benign and malignant ulceration. Epigastric pain or distress may be characteristic and rather frequent, and, indeed, 89 per cent of our patients with distress arising from malignant ulcers were relieved with food or alkali. In this series little difference was noted in duration of symptoms (table 4). Loss of weight was a prominent feature in both groups of cases. A weight loss of 5 to 50 pounds (2.3 to 22.7 Kg.) was noted in the series of benign ulcers, so that pronounced loss of weight was by no means an indication of cancer.

In general, the size of the ulcer did not present reliable evidence of its being benign or malignant, although the malignant ulcer in the majority of cases was larger (figs. 1 and 2). In this series, 61.5 per cent of the malignant ulcers were larger than 2.5 cm. (table 5), whereas only 27 per cent of the benign gastric ulcers were larger than 2.5 cm.

Table 6.—*Gastric Acidity (Ewald Test Meal)*

	26 Malignant Ulcers, Percentage	105 Benign Ulcers, Percentage
Acidity above 40	27	22.5
Normal, 15-40	61	50.5
Hypoacidity, below 15	4	14.0
Anacidity (without histamine)	8	13.0

Table 7.—*Site of Ulcer in Stomach*

	Malignant Ulcer Cases	Malignant Ulcer Percentage	Benign Ulcer Cases	Benign Ulcer Percentage
Prepyloric	12	46.1	41	39.4
Lesser curvature	10	38.5	63	60.0
Greater curvature	1	3.9	1	0.96
Cardia	3	11.5	0	0
Total	26		105	

Acid determinations were surprisingly parallel in both groups; free hydrochloric acid was present in patients with malignant lesions, and anacidity occurred in those with benign ulcers (table 6). The presence or absence of free acid has proved of no value in distinguishing between malignant and benign ulceration, but anacidity should make the examiner more strongly suspect malignancy.

With regard to the site of origin in the stomach and percentage of chronic ulcerating lesions, one does not find any remarkable differences, as one would expect. Although it is true that the largest group of benign ulcers occurs on the lesser curvature, yet there is a considerable number of benign lesions (39.4 per cent) in the prepyloric area, and this was also noted with regard to malignant ulcers (46.1 per cent, table 7). The only significant factors noted, and these should be emphasized again and again, are that malignant ulcerations can and do occur at any site in the stomach and every gastric ulcer should be regarded as malignant until otherwise proved. One is confronted constantly with similarities in symptoms, acidity, site of ulceration, age, and so forth. Although there are different clinical features suggestive of cancer, yet these differences are not definite enough or constant enough to allow one to establish definite criteria for diagnosis. All that one can say is that any gastric ulcer may be malignant, that all patients with prepyloric lesions, ulcers on the greater curvature and possibly the cardia should have surgical treatment and not medical treatment; again, that all patients with chronic or recurring lesions should have operation, and only an occasional patient with early acute gastric ulceration should have medical treatment. This treatment should not be persisted in if complete healing with relief of all distress is not obtained immediately.

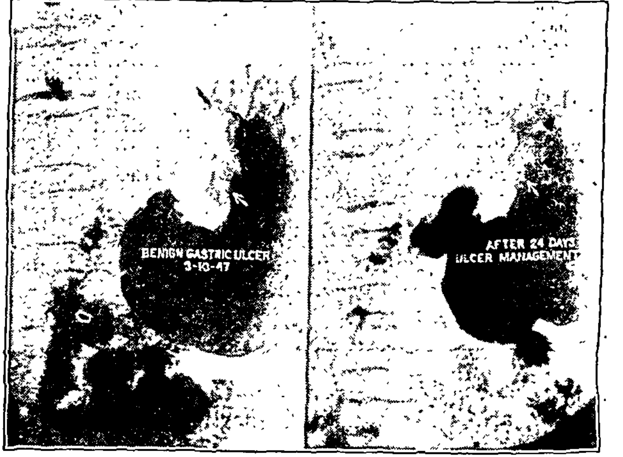

Fig. 1.—Large gastric ulcer occurring in woman, 58 years of age; malignancy suspected because of irregularity and size of defect and because of failure to heal under medical regimen; absence of free hydrochloric acid noted. Operation proved ulcer to be benign.

In the 105 cases of benign ulcers, certain salient features are of special interest. The indications for operation in this group are given in table 8. It is noteworthy that the most frequently occurring indication for operation was suspected cancer, 60.9 per cent in the series of 105 benign cases. Here, again, was incontrovertible evidence that the nature of the lesion so far as it pertains to cancer cannot be determined in a considerable number of cases save by operation and pathologic examination. Roentgen examination, however, will disclose the presence of ulcer but not its nature as relates to possible malignancy. Of 105 cases of benign ulcers the lesion was definitely demonstrated in 102 patients, or 98.1 per cent. Two patients had obstruction at the pylorus but no evidence of prepyloric ulcer, and 1 patient was operated on because of repeated massive hemorrhage. A prepyloric ulcer was found at operation but no ulcer could be demonstrated by roentgenologic examination. The indications for operation in both groups are surprisingly similar.

RESULTS FOLLOWING PARTIAL GASTRECTOMY

The results following partial gastrectomy for gastric ulcer are excellent. Eighty-six per cent of the patients had an absence of free hydrochloric acid after operation. There were no postoperative recurrent ulcers and no obstruction occurred in any case at the gastrojejunal stoma. Recurrent ulcer after an adequate partial resection of the stomach for gastric ulcer is a most infrequent complication. Recurrent ulcer, however, is not uncommon in those cases in which some operation other than radical gastrectomy is done, as is demonstrated by the fact that 12 of the 105 patients with proved benign ulcers had had previous operation (not partial resection) without relief of their symptoms and with definite evidence of recurrent ulcer (table 9).

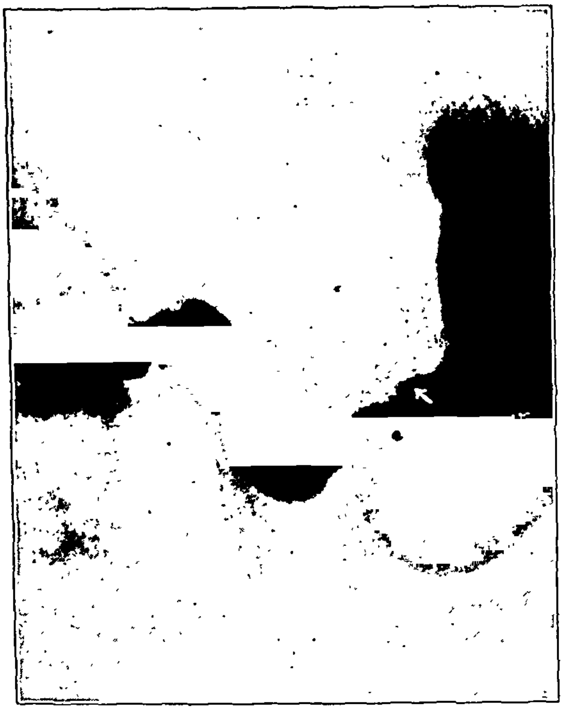

Fig. 2.—Carcinoma of stomach in man, aged 51 years. Small penetrating lesion, 2 cm. in diameter, of lesser curvature; free hydrochloric acid, 60. Operation proved ulcer to be malignant with metastasis to nodes.

Because of the difficulty in determining whether an ulcer is benign or malignant, and this can definitely be determined only by pathologic section, it is our opinion that no attempt should be made to treat any patient with gastric ulceration by resection of the vagus nerves. It is of primary importance that the ulcer be removed, and this preferably by partial resection of the stomach. In view of the fact that gastric ulcers rarely occur after resection there is no need for employing resection of the vagus nerves in addition to resection of the ulcer in this condition. One factor has made for hesitancy in removing certain types of ulcers by resection, and that is the location of the ulcer high on the lesser curvature of the stomach. The surgeon without considerable experience with gastric surgery may consider that the ulcer is situated too high for partial resection and apparently may require total gastrectomy for removal of the ulcer. This difficulty, however, is more apparent than real and in the majority of cases is the result of contraction of the gastrohepatic omentum along the lesser curvature because of fibrosis and infiltration with inflammatory exudate associated with these ulcers high on the lesser curvature. When the stomach has been adequately mobilized and the lesser curvature cleaned properly of all areolar and scar tissue, in the majority of cases there is sufficient normal stomach wall above the ulcer to permit gastrojejunal anastomosis without encroachment on the esophagus. We have seldom seen any particular difficulty arise with resection in such ulcers.

Table 8.—*Immediate Indications for Operation*

	26 Malignant Ulcers		105 Benign Ulcers	
	Cases	Percentage	Cases	Percentage

Recurrent ulcer..................	6	23.0	20	19.5
Intractable ulcer................	1	3.8	13	12.0
Pyloric obstruction............	3	11.5	6	5.7
Massive hemorrhage...........	0	....	2	1.9
Total........................	26		105	

In the last analysis, all patients with gastric ulcer are operated on because of inability to rule out cancer.

Walters and Clagett reported that only 1 patient in 162 cases followed after operation for gastric ulcer had had a poor result and this failure followed simple excision of the ulcer.

Only 1 patient in this series of benign ulcers has had recurrent gastric distress after operation. This patient had had a previous closure of a perforated ulcer and later a posterior gastroenterostomy done at the clinic. He was uncooperative, drank and smoked a great deal and refused to adhere to a reasonable diet which was not especially strict. Most patients within a few weeks or months after operation can eat an ordinary, full diet with few restrictions and with no gastric distress. All are relieved of ulcer distress and pain and all are able to return to work usually within three months after operation.

There were 3 deaths following resection, an operative mortality of 2.85 per cent in the group of 105 cases with benign gastric ulcers. Over a period of nine years during which ninety-six consecutive operations were done, however, there were no deaths (Sept. 15, 1936 to Sept. 15, 1945). Prior to September 1936, 1 death occurred from pulmonary embolism; since September 1945, 1 death was the result of pulmonary embolism, and 1 death followed a coronary occlusion.

SUMMARY

Gastric ulcer occurs less frequently than duodenal ulcer, a proportion of 1 to 9. It is more common in men than in women, a ratio of 4 to 1. The majority of ulcers in this series occurred in patients in the fifth decade or later.

In this series of 131 patients operated on with a diagnosis of benign ulcer, there were 26 malignant ulcers, a diagnostic error of 19.8 per cent in those patients having operation. The incidence of error in the entire group of patients with gastric ulcers treated medically and surgically was 3.3 per cent.

Although the majority of malignant gastric ulcerations (61.5 per cent) are larger than 2.5 cm., small ulcers can be and often are found to be malignant. Malignant ulceration may occur anywhere in the stomach but is found more frequently in the prepyloric area, on the greater curvature and in the cardial area. All patients with ulcers arising in these areas should have surgical treatment without further observation or any attempt at medical treatment.

The treatment of all patients with gastric ulcer should primarily be surgical in character; especially should all chronic and recurring ulcerations be resected.

Postoperative results in general are excellent. Recurrent ulcer after resection has not developed in any case. The clinical results are excellent. Mortality can be kept at a minimum, as is illustrated by ninety-six consecutive resections without a fatality.

COMPLICATIONS OF PEPTIC ULCER

With Special Reference to Treatment

HAROLD LINCOLN THOMPSON, M.D., Ph.D.
Los Angeles

Peptic ulcer has been the subject of discussion for nearly half a century. During that time noteworthy advancements in our knowledge have been made. There now is greater appreciation of the psychogenesis and the physiologic pathogenesis of peptic ulcer and thus a better understanding of the basically functional nature of the disorder. Since therapeutic empiricism ended about a generation ago, the principles of treatment have been practiced more in accordance with the scientific method. This applies especially to the complications of peptic ulcer wherein there exists the greatest general agreement as to the merits of medical or the necessity for surgical treatment. Present knowledge of the importance of nutrition, of mental and physical hygiene and a wider application of improved methods of medical and surgical treatment have brought about a relative but not an actual reduction in morbidity. Despite these advances there has not resulted a corresponding decrease either in the incidence of peptic ulcer or of its complications. Thus, in view of the currently high incidence and mortality, it is clear that there has been little real progress in the over-all solution of this problem. Thus abundant room remains for constructive work to be done and discussion must continue.

The complications of peptic ulcer are many and varied. They are the principal cause of mortality. They constitute the chief indications for surgery. A comprehensive clinical outline of the primary complications includes:

1. Perforation
    - Acute, into the peritoneal cavity
    - Subacute, with spontaneous closure by omental plug or adjacent viscus and the "formes frustes" type
    - Chronic penetration into adjacent viscera
2. Hemorrhage
    - Mild or moderately severe
        - Initial
        - Recurrent
    - Acute massive
        - Occurring before age 45
        - Occurring after age 45
3. Obstruction
    - *Acute intermittent, produced by edema and spasm*
        - Obstruction at the pyloric outlet
        - Hourglass obstruction in the body of the stomach
    - *Chronic progressive obstruction resulting from cicatricial stenosis*
        - Occurring at the pyloric outlet
4. Intractability
    - With reference to pain
    - With reference to disability
5. Malignant degeneration
    - Practically limited to gastric ulcer
        - Debatable

This outline does not include the conditions which complicate the complications. The most common secondary complications are malnutrition, anemia, shock, general and local peritonitis, wound infection with or without disruption and those occurring in the respiratory and vascular systems. It should be recalled here that two or more complications may exist simultaneously in a given case. In our recent series of surgically treated cases, multiple primary complications existed in 26 per cent.[1]

Prevailing opinion is that surgical treatment should be limited to the complications of peptic ulcer. Accordingly from a surgical point of view two groups of cases must be distinguished. The first group includes those complications characterized by insidious onset and chronic course in which the indications for surgical treatment are relative. The second group includes those cases which develop suddenly, threaten life and become surgical emergencies wherein the indications for surgical treatment are absolute. In accordance with this distinction, the present discussion will be confined to three common complications of peptic ulcer, namely, pyloric obstruction, acute hemorrhage and acute perforation.

PYLORIC OBSTRUCTION

Pyloric obstruction is a clinical term which refers to certain symptoms resulting from stenosis occurring in the region of the outlet of the stomach. In 118 deaths from peptic ulcer reported by Portis and Jaffe,[2] obstruction was responsible in 7.5 per cent of cases. Two types of obstruction are to be distinguished clinically. First, there is acute transitory functional obstruction which results from spasm or edema or both wherein the treatment is medical. Second, there is chronic pyloric obstruction resulting from organic cicatricial stenosis in which the treatment ultimately is surgical.

Some of the articles in this symposium are to be published in the *Archives of Surgery*.

Read in a symposium on Peptic Ulcer before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Gastro-Enterology and Proctology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

[1] Thompson, H. L., and Prout, H.: Surgical Treatment of Peptic Ulcer, Arch. Surg. **54**: 390-413 (April) 1947.

[2] Portis, S. A., and Jaffe, R. H.: A Study of Peptic Ulcer Based on Necropsy Records, J. A. M. A. **110**: 6-13 (Jan. 1) 1938.

Pyloric obstruction resulting from spasm or edema usually is associated with an active ulcer at or near the pylorus. Intermittently, spasm and edema occur as a direct result of ulcer activity. The obstructive symptoms are of the nature of acute transitory phenomena which respond to gastric decompression, rest and antispasmodics. Recurrences depend on the failure to control ulcer activity. By frequently repeated activity or as a result of healing of the ulcer, this type may gradually merge into the cicatricial variety.

Chronic pyloric obstruction resulting from cicatricial stenosis by contrast is the result of the formation of an excess of scar tissue. It results from prolonged or repeated activity of the ulcer or secondarily to the coexistence of multiple ulcers on adjacent walls of the pylorus or duodenum. In a considerable proportion of cases, the primary symptoms of ulcer long since have vanished and the ulcer is found to have disappeared. Scarring results from nature's attempt at ulcer healing and stenosis occurs from normal contractility of scar tissue. Situated at its narrow outlet, stenosis interferes with the normal emptying mechanism of the stomach.

The symptoms which ensue from either type of obstruction are retention or vomiting of food with ultimate depletion of the general nutrition of the patient. Eventually the patient seeks relief because of his inability to retain or absorb food as reflected in terms of loss of weight and starvation.

The diagnosis of pyloric obstruction is based on a history of peptic ulcer. Analysis of the behavior of the ulcer is helpful in differentiating the two varieties of obstruction. Characteristic ulcer distress usually is present when an active ulcer is responsible for spasm or edema. In chronic obstruction resulting from cicatricial stenosis the distress may have diminished or disappeared as obstruction supervened. In either type, physical examination discloses evidence of loss of weight with depletion of adipose and muscular tissues and may reveal enlargement of the stomach in which peristalsis may be visible. Roentgenologic examination confirms the gastric enlargement and barium is retained to an abnormal degree. The acidity of the gastric content may be low. Finally, differentiation may not be possible until the therapeutic response to gastric decompression, physiologic rest and antispasmodics has been observed.

Treatment.—In obstruction of either type the stomach must be decompressed by continuous suction during a period of bed rest while attention is directed toward the correction of deficiencies induced by protein and chloride depletion, anemia, dehydration, avitaminosis and hyperazotemia. If anemia is severe the transfusion of compatible blood may be necessary. Dehydration, hypochloremia and hyperazotemia may be corrected by the daily administration of 2,500 to 3,500 cc. of isotonic solution of sodium chloride intravenously. If plasma proteins are reduced to the critical level of 5.2 Gm. per hundred cubic centimeters, amino acids should be substituted for one or more liters of saline solution. Vitamin deficiency may be combated by the administration
of massive doses of ascorbic acid and vitamin B
plex. Antispasmodics in the form of belladonna d
tives administered in physiologic doses usually
effectual in stenosis resulting from spasm and
but not in cicatricial stenosis.

In cases of chronic cicatricial stenosis surgical treatment ultimately becomes necessary. Before resorting to surgery preparation of the patient as just described is mandatory. Until recently the simple relief of the mechanical derangement by means of pyloroplasty or gastrojejunostomy was thought to be sufficient. While the immediate results of these palliative measures were excellent, too frequently recurrences of ulcer activity or the appearance of anastomotic ulcer marred the permanency of the result. For this reason recent practice has been to employ subtotal gastrectomy wherein the distal two thirds to four fifths of the stomach are removed. The amount of stomach which it is believed necessary to resect to be effectual varies considerably in different clinics. Occasionally when the ulcer is situated at the pyloric ring, local edema or penetration makes it impractical to dissect the ulcer sufficiently for safe removal. Under these circumstances it may be desirable not to remove the portion of the stomach immediately proximal to the pyloric ring. In such instances, in order to control the humoral phase of gastric secretion, removal of the mucosa from the retained pylorus is mandatory.

My practice has been to resect not less than the distal two thirds of the stomach, to restore continuity by the Hofmeister-Polya procedure and to complete the anastomosis anterior to the colon in the antiperistaltic manner. That is, the divided end of the stomach is closed with sutures for one fourth to one third its diameter and end to side gastrojejunal anastomosis is completed so that the efferent limb of the jejunum is attached to the greater curve of the stomach. If under preoperative decompression the obstructed stomach has not returned fully to its normal size, care must be used in the application of the Hofmeister modification. One must not close too much of the divided end of the stomach lest obstruction ensue when the organ ultimately contracts to its normal size. Colleagues and I favor the Hofmeister modification because in our experience it prevents untoward functional results in two respects. It diminishes the tendency to dumping of food from the stomach into the jejunum and it prevents excessive regurgitation of duodenal juices into the stomach. We obviate the fatal angle simply by sealing off the closed divided end of the stomach by suturing the afferent limb of the jejunum over it.

Section of the vagus nerves, as advanced by Dragstedt, is the most recent development in the surgical treatment of peptic ulcer. The procedure now is in the phase of critical analysis. Dragstedt[3] has advised combining vagotomy with gastrojejunostomy as a safer and less radical procedure than subtotal gastrectomy in the treatment of pyloric obstruction. While the initial results of this procedure appear to be good, it probably is too early to evaluate them fully. Moreover, it appears that this procedure might be utilized to best advantage by limiting its use to active

shown that age is the most important factor in mortality in acute massive hemorrhage. He believes that it is dependent on arteriosclerosis in the wall of the bleeding vessel whereby its power of contractility fails. By employing operation within seventy-two hours, by limiting its use to patients who are 45 years of age or over and by utilizing a special technic of exposure under ideal surgical surroundings, Allen reported 1 death in a series of 9 cases. While this mortality is high as compared with the results of medical treatment in general, there is no question but that in his and other like series a few patients have been saved by operation who otherwise would have died. Moreover, there are unquestionably a few patients in whom surgical treatment with direct control of bleeding is the only available means of saving life. The problem lies in the proper selection of those cases and in the technical execution of the appropriate operative procedure on patients who are being supported by blood transfusions before, during and after operation.

Indications for Treatment.—Unfortunately in the early stage of bleeding there is no positive means of distinguishing between patients who will respond to medical treatment and those in whom surgical intervention ultimately will be necessary. The best means at our disposal is close observation of the clinical course. During this period factors which must be taken into account as a basis for the selection or rejection of patients for surgical treatment are several:

Age of Patient: Allen and Benedict[14] having shown that the most important factor in prognosis of hemorrhage from duodenal ulcer was age, in patients younger than 45 years the mortality on conservative treatment was less than 5 per cent. In patients older than 45 years the mortality was 30 per cent. Thus, on the basis of rather general acceptance of the age criterion, in the former group conservative methods should be continued because a mortality of less than 5 per cent fro surgical treatment cannot be expected. In the
oup, however, on the basis of age alone,
forty-eight hour rule should apply to good
vith the expectation of an improvement over
ity of 30 per cent from conservative treat-
atients or ted on after forty-eight hours,
enced a mortality of 30 per

ries,[4] 55 per cent of
al hemorrhage and the
from peptic ulcer was
21.6 per cent irrespective of the severity of the bleeding. Most studies indicate that the danger of fatality increases with each hemorrhage, particularly if the patient eventually reaches the critical age.

Severity of Hemorrhage: Emergency surgery should not be applied to hemorrhage from peptic ulcer in patients who present nothing more than occult blood in the stool, blood-stained or coffee-ground vomitus or persistent secondary anemia. Surgical treatment is to be considered only in patients who manifest vomiting of bright or dark red blood, grossly blood-stained or tarry stools and who lose blood sufficient to produce weakness, pallor, dyspnea, tachycardia and decided fall in blood pressure. Estimations of hemoglobin and red blood cells are less valuable early indicators, the hematocrit reading being the best index of quantitative blood loss. If, after multiple blood transfusions, the blood pressure remains below 90 systolic and the pulse rate over 130, there is evidence of continued bleeding and reason for concern for the life of the patient. On the other hand, certain patients respond so promptly to treatment that usually they can be classed early with the more favorable group. In patients who are under conservative treatment two factors indicate that they belong to the less favorable group; namely, the failure early to manifest signs of cessation of bleeding or the evidence that bleeding has recurred. Thus the patient's response to treatment while he is followed by half-hourly checks on pulse and blood pressure is the best criterion for the selection of cases in which surgical intervention is indicated. Emphasis is placed on the necessity for selection within the forty-eight hour period because after that interval the mortality is as high as 30 per cent.

Associated Disease: As is well known, patients past 45 years of age frequently manifest arteriosclerosis, hypertension, coronary sclerosis and other systemic disease. If secondary anemia is superimposed on these conditions, patients become poor operative risks. Within reasonable limits the presence of associated disease is an absolute indication for early operation, since pronounced uncorrected secondary anemia with attendant anoxia, hyperazotemia and hypoproteinemia is more likely to induce a fatal termination than is the operation which is performed to control the bleeding.

The indications for surgical treatment after recovery from hemorrhage are relative and cases therefore require individualization. This phase of the problem will not be discussed here except to emphasize that mortality increases with succeeding hemorrhages and with each hemorrhage the indications for surgical intervention become more definite.

Principles of Surgical Treatment.—Since severe hemorrhage must be regarded as potentially fatal, continued bleeding despite transfusion is the prime indication for surgical intervention. While continued transfusion keeps the patient alive for an indeterminate period, it does not prevent him from becoming so depleted that he no longer is a good surgical risk. The earlier the application of surgery the better the prospect of recovery. Hence the decision for surgical treatment must be early, and once it is made, a departure from it should not be contemplated.

The surgical treatment of acute massive hemorrhage involves direct attack on the bleeding area in order to check the hemorrhage. It requires adequate exposure

shown that age is the most important factor in mortality in acute massive hemorrhage. He believes that it is dependent on arteriosclerosis in the wall of the bleeding vessel whereby its power of contractility fails. By employing operation within seventy-two hours, by limiting its use to patients who are 45 years of age or over and by utilizing a special technic of exposure under ideal surgical surroundings, Allen reported 1 death in a series of 9 cases. While this mortality is high as compared with the results of medical treatment in general, there is no question but that in his and other like series a few patients have been saved by operation who otherwise would have died. Moreover, there are unquestionably a few patients in whom surgical treatment with direct control of bleeding is the only available means of saving life. The problem lies in the proper selection of those cases and in the technical execution of the appropriate operative procedure on patients who are being supported by blood transfusions before, during and after operation.

Indications for Treatment.—Unfortunately in the early stage of bleeding there is no positive means of distinguishing between patients who will respond to medical treatment and those in whom surgical intervention ultimately will be necessary. The best means at our disposal is close observation of the clinical course. During this period factors which must be taken into account as a basis for the selection or rejection of patients for surgical treatment are several:

Age of Patient: Allen and Benedict[14] having shown that the most important factor in prognosis of hemorrhage from duodenal ulcer was age, in patients younger than 45 years the mortality on conservative treatment was less than 5 per cent. In patients older than 45 years the mortality was 30 per cent. Thus, on the basis of rather general acceptance of the age criterion, in the former group conservative methods should be continued because a mortality of less than 5 per cent from surgical treatment cannot be expected. In the second group, however, on the basis of age alone, Finsterer's forty-eight hour rule should apply to good risk cases with the expectation of an improvement over the mortality of 30 per cent from conservative treatment. In patients operated on after forty-eight hours, however, Finsterer experienced a mortality of 30 per cent.

Advance Knowledge of Presence and Location of Ulcer: It is extremely helpful in these emergencies if previous examination has disclosed the presence and location of peptic ulcer Otherwise it often is impossible to localize the lesion during active bleeding. While fatal hemorrhage from superficial ulcers in other locations does occur, the largest number result from erosion of the pancreaticoduodenal artery or one of its branches by penetrating ulcers on the posterior wall of the duodenum. Thus patients who are known to have chronic penetrating ulcers in this location and in whom gross hemorrhage occurs are likely candidates for immediate surgical treatment.

Initial or Recurrent Hemorrhage: It is important to recall that the initial hemorrhage may be the fatal one. Thus, in our recent series,[4] 55 per cent of patients were admitted for initial hemorrhage and the gross mortality in hemorrhage from peptic ulcer was 21.6 per cent irrespective of the severity of the bleeding. Most studies indicate that the danger of fatality increases with each hemorrhage, particularly if the patient eventually reaches the critical age.

Severity of Hemorrhage: Emergency surgery should not be applied to hemorrhage from peptic ulcer in patients who present nothing more than occult blood in the stool, blood-stained or coffee-ground vomitus or persistent secondary anemia. Surgical treatment is to be considered only in patients who manifest vomiting of bright or dark red blood, grossly blood-stained or tarry stools and who lose blood sufficient to produce weakness, pallor, dyspnea, tachycardia and decided fall in blood pressure. Estimations of hemoglobin and red blood cells are less valuable early indicators, the hematocrit reading being the best index of quantitative blood loss. If, after multiple blood transfusions, the blood pressure remains below 90 systolic and the pulse rate over 130, there is evidence of continued bleeding and reason for concern for the life of the patient. On the other hand, certain patients respond so promptly to treatment that usually they can be classed early with the more favorable group. In patients who are under conservative treatment two factors indicate that they belong to the less favorable group; namely, the failure early to manifest signs of cessation of bleeding or the evidence that bleeding has recurred. Thus the patient's response to treatment while he is followed by half-hourly checks on pulse and blood pressure is the best criterion for the selection of cases in which surgical intervention is indicated. Emphasis is placed on the necessity for selection within the forty-eight hour period because after that interval the mortality is as high as 30 per cent.

Associated Disease: As is well known, patients past 45 years of age frequently manifest arteriosclerosis, hypertension, coronary sclerosis and other systemic disease. If secondary anemia is superimposed on these conditions, patients become poor operative risks. Within reasonable limits the presence of associated disease is an absolute indication for early operation, since pronounced uncorrected secondary anemia with attendant anoxia, hyperazotemia and hypoproteinemia is more likely to induce a fatal termination than is the operation which is performed to control the bleeding.

The indications for surgical treatment after recovery from hemorrhage are relative and cases therefore require individualization. This phase of the problem will not be discussed here except to emphasize that mortality increases with succeeding hemorrhages and with each hemorrhage the indications for surgical intervention become more definite.

Principles of Surgical Treatment.—Since severe hemorrhage must be regarded as potentially fatal, continued bleeding despite transfusion is the prime indication for surgical intervention. While continued transfusion keeps the patient alive for an indeterminate period, it does not prevent him from becoming so depleted that he no longer is a good surgical risk. The earlier the application of surgery the better the prospect of recovery. Hence the decision for surgical treatment must be early, and once it is made, a departure from it should not be contemplated.

The surgical treatment of acute massive hemorrhage involves direct attack on the bleeding area in order to check the hemorrhage. It requires adequate exposure of the ulcer so as to ligate the vessels before they enter the ulcer bed. Local, indirect or palliative attempts to control the hemorrhage are the least dependable. In duodenal hemorrhage the technic of Allen[11] is to divide the stomach through the distal third. The anterior wall of the stomach then is incised longitudinally in order to expose the ulcer and control the bleeding by direct digital pressure. When the hemorrhage is brought under control, the vessels are ligated beyond but not within the inflammatory area. The papilla of Vater is then visualized and a general survey is made to determine whether or not removal of the ulcer is a safe procedure. Subtotal gastric resection then is carried out according to the Polya or Billroth II method. In gastric ulcer it is necessary to open the anterior wall of the stomach in order to visualize and digitally compress the vessels. The vessels are ligated in normal tissue beyond the ulcer, after which one has the choice of proceeding with resection if the patient's condition permits or of closing the incision in the stomach, resection being completed at a subsequent stage.

---

[14] Allen, A. W., and Benedict, E. D.: Acute Massive Hemorrhage from Duodenal Ulcer, Ann. Surg. 98: 736-749, 1933.

Postoperative Care.—If subsequent to operation transfusions of blood are employed, it is necessary to check the Rh factor to avoid transfusion reaction. Fluid balance should be maintained and massive doses supplied of vitamins K, C and B. Frequent determinations of serum protein should be made lest deficiencies prevent healing of the wound and promote infection. When serum protein reaches the critical level of 5.2 Gm. per hundred cubic centimeters, replacement must be attempted by the administration of plasma or preferably amino acids.

Successful treatment of severe hemorrhage from peptic ulcer, therefore, involves competent clinical observation preferably on a cooperative medical and surgical basis. Abundant blood must be available for administration when necessary and the response to this treatment must be checked by half-hourly recording of pulse and blood pressure. If surgery is employed, success depends on experience in gastric surgery, wherein the procedure must be carried out with decision and facility.

ACUTE PERFORATION

Acute perforation of peptic ulcer results from extension of the ulcer process through all coats of the viscus, allowing escape of its content into the general peritoneal cavity. DeBakey[16] has shown that there is an apparent increase in incidence of this complication. In 33,439 collected cases occurring in the decade prior to 1940, he found 13.2 per cent of acute perforations. This complication occurs more commonly in males in the third to fifth decades, but has been reported in infants as young as 2 days old. I reported[17] 3 cases occurring in patients over 81 years of age.

As pointed out in a previous communication,[17a] acute perforation is the most sudden, the most severe and the most immediately disabling complication of peptic ulcer. In that study it was shown that the most characteristic symptom of acute perforation is pain. The onset of pain was sudden and intense, and, regardless of the time of the admission of the patient, it was localized in the upper part of the abdomen in 58 to 92 per cent of cases. When recorded, pain was referred to the shoulders in 89.8 per cent of cases. The most important physical finding was abdominal rigidity, which was described as extreme or boardlike in character, in 69.3 per cent of cases. Thus in the typical case of acute perforation of peptic ulcer, there does not exist a difficult diagnostic problem. In fact, the diagnosis in typical cases is so easy that an error is usually the result of inexperience, haste or oversight on the part of the examining physician. Nevertheless, despite the ease of diagnosis in typical cases, there exists a varying proportion of cases which in one or more respects are atypical and in which the establishment of a working diagnosis is difficult.

A point deserving of special mention in the clinical picture of acute perforation is shock. In the early stage of acute perforation pallor, cold moist skin and subnormal temperature often are referred to inclusively, without reference to the patient's blood pressure, as shock. I have shown[17] that whereas these superficial features of shock are present in 72.8 per cent of cases, its existence as confirmed by blood pressure readings regardless of the time of admission of the patient is present in only 19.2 per cent of cases. These observations have been confirmed by Soutter[18] and others.

Treatment.—Less controversy exists regarding the treatment of acute perforation than in any of the complications of peptic ulcer. In most quarters the diagnosis or suspicion of acute perforation is an absolute indication for surgical intervention. Thus closure of the perforation is indicated by common consent at the earliest possible moment. Except for the fact that closure interrupts continued peritoneal soiling, the mechanism by which it brings about recovery is not well understood. The observation that certain atypical forms of acute perforation including the "subacute" type of Lund,[19] the "intermittent leakage" type of Singer[20] and the "formes frustes" type of Singer and Vaughan[21] do well without surgical intervention has led to the concept of nonoperative treatment of perforated ulcer as reservedly advanced by Wangensteen[22] and by Taylor.[23] While Wangensteen emphasized the fact that there can be no debate about the advisability of closure of the perforation in early cases, he stated that patients in whom there are indications of but slight peritoneal soiling, signs of the "formes frustes" type of ulcer or diffuse generalized peritonitis of over twenty-four hours' duration may be treated best by continuous suction applied to an inlying duodenal tube. The Ochsner treatment of peritonitis as outlined by Taylor should be applied, including the regular administration of morphine, intravenous fluids and chemotherapy. The experience of Jackson and Metheny,[24] Barbour and

Madden[25] and Olson and Norgore,[26] however, indicates extremely high mortality following nonoperative treatment. From this it must be assumed that patients who are to receive this treatment must be selected with extreme and discriminating care. As pointed out by Allen, longer time must be allowed in order to evaluate this method of therapy.

Surgical Treatment.—There being general agreement on the value of surgical treatment properly applied, it appears that if further reductions in mortality are to be anticipated, close attention to the technical details must be observed.

Anesthesia: In patients who are in good condition spinal anesthesia generally is preferred. Paradural analgesia should prove satisfactory but its administration is time consuming, and with reference to perforated ulcer it has not had extensive consideration in the literature. In patients who are in poor condition, intratracheal inhalation anesthesia employing nitrous oxide or cyclopropane after induction with "pentothal sodium" is to be preferred. Curare assists in securing adequate relaxation without employing excessive amounts of the anesthetic agent. In patients who are in very poor condition, field block may be employed if surgery is to be utilized at all.

Abdominal Incision: Because serious and sometimes fatal infection or disruption of the wound occurs after operation for acute perforation, attention has been given in recent years to the type of abdominal incision.[27] Instead of the usual longitudinal incision oblique or transverse incisions have been utilized employing the muscle-splitting principle. The advantages claimed for such incisions are that the wounds are more easily closed, after which early ambulation may be employed with greater safety and with resulting shorter periods of hospitalization.

Peritoneal Culture: The taking of routine peritoneal cultures at the time of operation as recommended by many[28] yields interesting results from a clinical and prognostic standpoint. In general, positive cultures are obtained in about 50 per cent of cases, from which it may be deduced that in early operation negative cultures are not uncommon. The organisms most frequently encountered are the colon bacillus, the Streptococcus and occasionally the Staphylococcus. When positive cultures are obtained, the reported mortality ranges from 30 to 70 per cent.

Closure of Perforation: With reference to the method of closure of the perforation, it is generally agreed that the best procedure is simple closure reinforced by fixation of a tag of omentum over the suture line. Thus in our series[29] there was a difference in mortality of nearly 10 per cent between the groups of cases in which the closure was completed with and those without the tag of omentum. Special methods of closing the perforation have been devised.[30] In experimental work on dogs, Price and Tunnie found that living omental patches were highly resistant to digestion and infection and that they allowed gastric defects ample time to heal. Their results were not good when omental transplants bereft of blood supply were utilized. Without attempting to close the opening with sutures, Graham closes the perforation simply by tying a tag of living omentum over it. Baritell's method is similar. Gatch and Owen's method is to place a row of silk sutures in healthy stomach and duodenal tissue well beyond the limits of induration. After these sutures are laid down the walls are pulled together, thus deeply infolding the ulcer. The addition in conjunction with closure of such other procedures as pyloroplasty and gastrojejunostomy practically has been abandoned because of poor results from these procedures. In accordance with Graham's dictum, "the surgeon's responsibility is solely to save life and to do this with the most simple and minimal surgical procedure that will accomplish that end."

Numerous instances have occurred at operation in which the perforation already has been closed by a tag of omentum. It now is rather well known that in such instances it is not only desirable but imperative not to disturb the tag of omentum or to attempt to close the perforation with sutures.

Gastric Resection: Follow-up studies indicate that subsequent to suture of acute perforation of peptic ulcer recurrence of symptoms is frequent. In our series,[29] follow-up for periods up to eighteen months was possible in 41 per cent of cases. While 68 per cent of patients in this group claimed to have been completely relieved by operation, approximately 32 per cent required further medical treatment and 8 per cent further surgical treatment within that period. In an effort to improve the late results of surgical treatment of acute perforation certain writers, particularly of the European school, have advocated subtotal resection as a primary operation.[31] While these writers claim low operative mortality and superior end results, the best opinion in this country seems to be that gastric resection should be applied as a second stage procedure if needed when the patient is in better condition to withstand it.

Drainage of Peritoneal Cavity: Whereas in the past it was common practice to drain the peritoneal cavity, the practice has been abandoned almost entirely in favor of thorough aspiration at the time of operation and tight closure of the abdominal incision. Special attention was given to this point in my previous report.[29] In the group of patients in which drainage was not used the mortality was 14 per cent. In cases in which single drains were utilized the mortality ranged from 19.7 to 32 per cent, whereas in cases in which multiple drains were employed, the mortality was 34.4 per cent. Thus the lowest mortality resulted in those cases without drainage and the mortality increased in direct proportion to the number of drains employed.

The employment of sulfonamide compounds in the peritoneal cavity has received the attention of numerous writers.[32] While at the time of their writing certain authors were favorably impressed, convincing statistical proof was not adduced by any of them, and some writers stated that they were "not impressed" by their use. While it is difficult to check on this point in the literature, my feeling is that the practice probably has been abandoned almost entirely in favor of parenteral administration of sulfonamide compounds and antibiotics before and soon after operation.

Surg. **120**: 60-65, 1944.

Wound Closure: Because of the frequency with which wound infection and wound separation is reflected in terms of mortality, attention has been given not only to the type of incision but also to the method of wound closure. Meade[33] found that in cases in which all layers of the wound except the skin were closed with surgical gut, there was primary wound healing without drainage in 74 per cent. While there was little or no correlation between the amount of intraperitoneal fluid and the interval between perforation and operation, the character of the fluid was important to the extent that when the fluid was frankly purulent primary healing occurred in only 50 per cent of cases. Barbour and Madden[25] usually close the wounds in layers without drainage, using black silk, but occasionally they employ through and through sutures of heavy silk. Black and Blackford[31] have advocated a combination of layer closure with surgical gut reinforced by through and through nonabsorbable sutures. In a recent study we[1] found that in 71 cases in which layer closure of the wound with surgical gut, cotton or steel wire was utilized there was a mortality of 9.8 per cent. In 29 cases in which through and through closure of the wound with wire, cotton or silk was employed, the mortality was 27.5 per cent. Through and through closure, however, was employed in cases which seemed at the time of operation to have a poor prognosis.

Postoperative Care.—Postoperative care is extremely important. Continuous gastric suction should be employed until danger of leakage at the point of closure is passed, the possibility of obstruction is eliminated and normal peristalsis ensues. Intravenous administration of fluids consisting of 5 per cent dextrose in isotonic solution of sodium chloride or water in sufficient amount that the patient's urinary output is at least 1,500 cc. per day should be utilized. Amino acids should be administered to the older patients, those in poor nutrition, those with bacterial peritonitis and when hypoproteinemia is present. Sulfadiazine should be administered intravenously along with sufficient sixth-molar sodium lactate solution daily to maintain urinary alkalinity and until the patient is free of signs of bacterial peritonitis or until he can take the drug orally. Penicillin may be employed if the bacterial culture indicates that it should be used. Morphine is essential but should be used with discretion lest fluids collect in the lungs and bronchi. In fact, special attention must be paid to the patient's respiratory and circulatory systems. The patient's position should be changed at least every two hours, and he should be encouraged to exercise his legs while in bed. Early ambulation should be employed except when bacterial peritonitis is present. In the first twenty-four to seventy-two hours deep inhalations of carbon dioxide at one-half to two hour intervals should be employed and coughing should be encouraged. Tracheal aspiration by catheter or bronchoscope should be used to remove bronchial exudate if the patient cannot expectorate it.

Mortality.—As compared with fifty years ago there has been a decided reduction in mortality in the surgical treatment of acute perforation of peptic ulcer. According to DeBakey[16] between the years 1897 and 1901 mortality ranged from 48 to 91 per cent. While some authors reported extremely low mortality rates,[35] the results of operation in large general hospitals in the United States are fairly uniform. Thus in 1939,[29] I reported from the charity services of Los Angeles hospitals a mortality in surgically treated patients of 28.7 per cent. Recently in material from the same source,[1] the mortality was 15 per cent. As pointed out by Baritell,[30a] there is no doubt but that if it were possible to employ the ideal procedure in every case the mortality could be reduced at least by 10 per cent.

Late Results: There is a general feeling that from 50 to 60 per cent of patients are relatively free of symptoms after suture of an acute perforation of peptic ulcer. Thus Wakeley[36] found that 44 per cent of 103 cases were able to perform military service. Williams,[37] reporting a follow-up of 100 cases from the Boston City Hospital, reported excellent to good results in 55 per cent of cases. On the other hand, Houston[38] noted recurrence of symptoms in 62 per cent of cases and found that 20 per cent of patients required further surgical treatment. Harrison and Cooper[39] reported persistent ulcer symptoms in 82.5 per cent and Estes and Bennett[40] in 94.4 per cent. With wide variations reported in the percentages of beneficial results as compared with the complete relief of symptoms, it seems best to agree with the statement of Black and Blackford[31] that the patient with ulcer after perforation should be considered in the same light as other patients with peptic ulcer.

CONCLUSION

An outline of complications of peptic ulcer has been presented. The incidence, clinical features, diagnosis and indications for conservative and surgical treatment have been discussed. Elective surgery having been discussed by other collaborators in this symposium, special attention has been directed toward the surgical treatment of pyloric obstruction, acute hemorrhage and acute perforation into the free peritoneal cavity. While indications for surgical treatment in these complications range from relative to absolute, attention has been directed toward the absolute indications wherein surgery is applied as a life-saving measure. Only by frequent and recurring discussion is there hope of reduction of the persistently high mortality in complications of peptic ulcer.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. FELDMAN, RAFSKY, WEINGARTEN AND KRIEGER, WALTERS, NEIBLING, BRADLEY, SMALL AND WILSON, MARSHALL AND WELCH, AND THOMPSON

Dr. Lester R. Dragstedt, Chicago: The discovery by Dr. Wangensteen and his associates that if an excessive, continuous secretion of gastric juice is produced in experimental animals peptic ulcers regularly appear in the stomach and duodenum is of great significance in the clinical problem. Evidence is gradually accumulating that a similar, abnormally large secretion of gastric juice is characteristic of the empty stomach of patients with duodenal ulcers. The control studies of Dr. Levin are especially valuable in this connection. We have found that this excessive secretion of gastric juice is neurogenic in origin and is abolished by complete division of the vagus nerves to the stomach. So far, we have not encountered a patient with duodenal ulcer whose excessive gastric secretion was on a hormonal or chemical basis. The observation that the excessive gastric secretion which occurs in patients with ulcer is neurogenic in origin and is abolished by gastric vagotomy constitutes the physiologic basis for this operation in the treatment of peptic ulcer. The cause of the secretory hypertonus of the vagus nerves in this disease is still obscure. The observations of Dr. Feldman are here of great interest. It may well be that long continued mental effort and strain, with perhaps an emotional content, may produce this hypertonus of the vagus nerves and that it is in this way that the central nervous system plays its role in the disease. During the past year, I have on several occasions heard Dr. Walters tell of his experience with the type of gastric vagotomy that he employs in the treatment of peptic ulcer, and I am convinced now that he does not like the operation that he has been performing: I must confess that I agree with him—I do not like it either. In my experience, a complete division of the vagus nerve fibers to the stomach can only be secured if these nerves are attacked along the lower part of the esophagus. The operation which Dr. Walters is performing represents an attempt to secure a complete vagotomy by cutting these nerves along the stomach. This is a procedure similar to that described by Stierlin and Schiassi many years ago and is almost certain to be incomplete. I should like to emphasize that in our hands, the operation is a supradiaphragmatic section of the vagus nerves, both when the operation is made through the abdomen and when it is made through the left side of the chest. In each instance, the vagus nerves are divided along the lower part of the esophagus, approximately 5 cm. above the stomach. The clinical results obtained have been more favorable than those secured by any other method with which I am familiar.

Dr. Sara M. Jordan, Boston: There is need for this symposium for three reasons: (1) because of the use of enterogastrone, (2) because of the use of vagotomy and (3) because this question of operation on all gastric ulcers has again arisen and should be discussed. The American Gastro-Enterological Association now has a committee to study the problem of ulcer nationally, and I am authorized by Dr. Harry Bockus, who has just supplanted Dr. Walter Palmer as our new president, to state that two subcommittees are being formed to study both vagotomy and enterogastrone intensively throughout the country. With regard to the question of whether all gastric ulcers should be operated on, Dr. Marshall hinted that there might be disagreement in our clinic on this point. The disagreement is more apparent than real because we are all gastroenterologists and surgeons intensely interested in the effort to improve the detection of carcinoma of the stomach and to obtain the earliest surgical treatment possible in cases that are malignant or can justifiably be suspected of malignancy. The arguments for the use of surgery in all gastric ulcers are that with increased skill of experienced surgeons and resultant decreased mortality surgical treatment is much safer. Dr. Marshall's latest figures would have convinced you of the improved risk, and that is, I believe, common experience, that subtotal gastrectomy now has a very low mortality. This, of course, was not true in the days when we struggled to save gastric ulcers from surgical treatment, if we thought that they could possibly be benign. Furthermore, our experience shows that there is a definite incidence of cancer, of change to cancer, in the unhealed and in the recurrent ulcer, and both surgeons and gastroenterologists have no question of that. In our records we have cases in which there was a presumably benign ulcer many years before the patient had a recurrent lesion in that same area which was malignant. That original ulcer healed and the patient was well in the meantime, but in that same area there was a return of the lesion which was then malignant. These cases indicate, we believe, that with recurrence there may be a change from benignity to malignancy. Against the idea that all gastric ulcers must be resected at once, we gastroenterologists ask ourselves, Shall gastric physiology be—I was going to use the word "sacrificed," but I think that the surgeons would object to that word—but shall it be mutilated in any way in all stomachs where there is a gastric ulcer? Shall this occur even though in our experience of twenty-four years (and many of our cases we have followed for a good many years) we find many instances of healing of the original ulcer and no recurrence throughout twenty-four years?

Dr. Ralph Colp, New York: Our results at the Mount Sinai Hospital, New York, were comparable to those of the Mayo Clinic. Our first 33 cases were transthoracic; the remaining 57 cases were intra-abdominal. We are convinced that the vagi may be effectively visualized and adequately divided by this approach. Moreover, it affords an opportunity to verify the local pathologic changes and perform a thorough exploratory examination. The insulin test revealed that in the majority of patients the nerve had been completely severed. There appears to be no relationship between the completeness and incompleteness of the vagotomy and the relief of pain, the acidity figures, the motor disturbances and the other complications. A synopsis of 21 cases of uncomplicated chronic duodenal ulcer which were intractable to medical treatment, many with hemorrhage but none with demonstrable obstruction, shows that the ulcer pain was eliminated in all but 1, which required operation two months later, and in spite of a negative insulin reaction on two occasions, an active ulcer on the posterior wall of the duodenum was present. Motor disturbances were the general rule, but they were so severe in 4 that these patients begged for relief because of epigastric distress, vomiting and the belching of foul gas. Exploration revealed that the ulcer had healed, that the pylorus was patent and that the stomach was dilated. The symptoms were relieved by a subtotal gastrectomy in 3 cases, and a gastroenterostomy in 1. Because the results were so unpredictable and variable, we have discontinued vagotomy as a sole procedure in the treatment of duodenal ulcer. We feel that vagotomy in gastric ulcer should never be done because it is impossible to tell whether an ulcer is benign or malignant. Subtotal gastrectomy removes the lesion, and the results over the past twenty-five years have been so excellent that we see no reason to discard it. A series of patients with duodenal ulcer were treated by combined operation. If gastric atony is so common following vagotomy, would not the best interests of these patients be served by the performance of a routine gastroenterostomy in vagotomy cases? We are doing gastroenterostomy and vagotomy in a control series of 25 cases, 19 having been done to date, many in old patients we deemed not suitable for subtotal gastrectomy. The motor difficulties in these cases have been transient. If the follow-up results over the next five to ten years reveal a lowering of the incidence of gastrojejunal ulcers following gastroenterostomy, then subtotal gastrectomy as a procedure for duodenal ulcer will probably be discarded.

Dr. Asher Winkelstein, New York: I have been studying the nocturnal gastric secretion since 1928. In 1931 I reported that the gastric secretion during the night was high in volume and acidity in patients with duodenal ulcer as contrasted with normal persons. All the methods used to control the night acidity before retiring and during the day failed. I therefore proposed at that time the continuous intragastric drip therapy which does control the night acidity. Since then many other observers, namely, Norporth, Henning, Chalfen, Dragstedt and Valdex, have confirmed these findings. Recently there has arisen the dissenting voice of Dr. David Sandweiss, who claims that normal persons and patients with ulcer have a similar nocturnal secretion. We disagree with Sandweiss' findings for the following reasons: 1. His test supper was too heavy and too stimulating. 2. He utilized ambulatory patients with very mild ulcer for study. 3. In his normal controls he upset, by using continuous suction, the duodenal regulatory inhibitory mechanism. We are therefore greatly pleased to hear today that this excellent study by Dr. Ervin, from Dr. Walter Palmer's clinic, once again confirms our original findings, an increased volume and acidity in patients with duodenal ulcer as contrasted with normal persons. The low acidity which is found so frequently in gastric ulcers is probably due to the associated gastritis occurring in the secretory area of the stomach. I have demonstrated that the best, in fact perhaps the only, medical method to control completely the night acidity is my continuous intragastric drip therapy with milk and calcium hydroxide solution or aluminum hydroxide gels. Enterogastrone in the dosage used does not control gastric acidity. Recently in a series of studies I found that the Co Tui protein hyperalimentation therapy also does not control the night acidity. Lester Dragstedt has demonstrated that surgically the best method of controlling the night acidity is complete bilateral vagotomy. We have studied the results of vagotomy and found that vagotomy alone lessens the night acidity and the volume by 50 per cent, but gives no night achlorhydria. The combination of gastroenterostomy and bilateral vagotomy gives 53 per cent night achlorhydrias. The combination of subtotal gastrectomy and bilateral vagotomy gives the startlingly good figure of 94 per cent night achlorhydria and 83 per cent day achlorhydria. Since we believe in the following dicta, "no acid—no ulcer," "control acid—healing of ulcer," "no postoperative acid—no recurrent ulcer," we advocate, medically, the control of the harmful night acidity secretion by the continuous intragastric drip therapy, and, surgically, the control of the harmful night and day acidity by the combination of subtotal gastrectomy and bilateral subphrenic vagotomy.

Dr. H. B. Stone, Chicago: I fear that we cannot make comparable report of such an admirably low mortality rate as Dr. Marshall has indicated. Our mortality rate would be somewhat higher than his. The most striking single figure reported by Dr. Marshall has nothing to do with the things I have just enumerated. It concerns the fact that in approximately 130 cases diagnosed by the most careful study as presumably benign gastric ulcers, operation has demonstrated actually that pathologically malignant lesions were present, and that, I take it, is the central theme of the paper of Dr. Marshall and the most important message that he brought to us today. I should like to report a single case which bears on this same problem. Some fifteen years ago, I operated on a man who was then 33 years old. I resected a small prepyloric ulcer, resection being inadequate as compared with present day standards. My diagnosis was a simple ulcer, and that was the laboratory report. In about ten months the patient began to show failing health, and on roentgen study it was apparent that he had been the victim of malignant extensions. Then the pathologist hunted up the block of tissue. Further sections were cut, and this time a clearcut diagnosis of carcinoma was made. I cite that case as to me being more significant than mere figures. Here was a patient who presented a lesion that a reasonably experienced surgeon on examination accepted as being benign, and a good pathologist on primary section accepted as being benign, yet the clinical course and the later pathologic investigation proved it to be unequivocally a malignant lesion. I agree with Dr. Marshall that there are very few cases of gastric ulcer which require total gastrectomy for the adequate removal of the lesion I hope that we will adopt the general use of the term "partial gastrectomy" for this type of operation. Dr. Marshall did not comment on the type of restoration that he used after gastric resection, and I take it from other publications from the Lahey Clinic that they are utilizing the antecolic Polya type of operation, or modifications of the Polya repair. That is our procedure, and we find it more satisfactory than any other method of reconstruction. The main point in Marshall's paper, is that there is grave danger of malignancy in supposedly benign gastric ulcers. The unavoidable lesson may be stated thus: Whereas duodenal ulcer is properly regarded as primarily best treated by medical measures, with certain exceptional cases requiring surgical handling, gastric ulcer should be considered primarily a surgical problem, with certain exceptional cases suitable for medical treatment.

Dr. J. William Hinton, New York: In principle, I agree with every point Dr. Marshall has made. I have, in the two clinics with which I have been associated—one for twenty years and another for ten years—followed the principles in every detail which he outlined and the points which he has enumerated. Within the past two years I have come to the conclusion which Dr. Marshall has stressed, that in many gastric lesions one can never be sure that they are benign, and perhaps more should be operated on. Of course, the problem which we all have is that of being accurate in our diagnosis. It is obvious from his report that 33 per cent of all the so-called ulcers had actually early malignancy. For the past few months we have been interested in trying to diagnose some of these lesions by gastric lavage, and Dr. McKenzie has used the technic of Papanicolaou, which he used for uterine cancer, and has applied it to washing from the stomach to get malignant cells, and to date we have had 39 cases. Dr. McKenrie knows nothing about the patients or their history; he is merely giving the gastric washings. For those patients he has reported twenty-four positive results, and of the twenty-four positive results, twenty-two were correct and two were in error. He reported fifteen negative results, and of these eight were incorrect. That is not bad, because those were cases of scirrhous carcinoma. There were no ulcerating lesions, and it was obvious that one could not get malignant cells from the gastric lavage. I think it is even more important that Dr. McKenzie, who is a gynecologist, had never seen cells of the gastrointestinal tract, and I think it possibly offers some help in making the early diagnosis in the debatable gastric lesions.

Dr. H. C. Saltzstein, Detroit: We have had through the course of a number of years a rather large series of dogs with Mann-Williamson ulcers which either were followed as controls with no medication or were given various medications, in the hope of modifying the course of the ulcer. We tried to see what effect a vagotomy would have on these dogs. A series of 28 control dogs survived the Mann-Williamson operation an average of seventy-one days. Twelve dogs who had vagotomy plus Mann-Williamson operation survived a much shorter period of time; that is, fifty-one days following the Mann-Williamson operation and forty-four days following vagotomy. (The vagotomy was usually, but not always, done after convalescence from the Mann-Williamson operation). Of the controls, 100 per cent showed ulcer at autopsy and 72 per cent of these died of perforation with peritonitis. Of the vagotomized animals, 6 of the 8 who lived more than one month after the Mann-Williamson operation had jejunal ulcers. An inflammatory reaction of varying severity was found in the upper part of the jejunum in 7 of these 12 dogs. There was no correlation with survival time. If it should be found to exist in patients after vagotomy, it might explain the diarrhea which at times follows this surgical procedure. Gastric dilatation was present in 9 of the 12 Mann-Williamson dogs who had vagotomy. This occurred more frequently in dogs with short survival time, but 1 animal showed decided gastric dilatation one hundred and eighty-two days after vagotomy and the Mann-Williamson operation.

Dr. Otto De Muth, Vancouver, British Columbia, Canada: I thank you for the Canadian surgeons who have been privileged to attend this magnificent session of the centennial of the American Medical Association. I am sure we have all enjoyed the high standard of the scientific papers that have been presented. We have learned much from our distinguished American confreres. The psychiatric, medical and surgical treatment of peptic ulcer has one objective: the lowering of hydrochloric acid in the stomach. This, to my mind, is attacking the problem of peptic ulcer from only one side. I would suggest that we treat peptic ulcer with the most effectual alkaline juice of the gastrointestinal tract—pancreatic juice. Pancreatic juice is capable of neutralizing the highest concentration of hydrochloric acid that the stomach is able to produce. Professor Ivy, in the December issue of The Journal of the American Medical Association, suggested that in peptic ulcer we want to raise the resistance of the mucous membrane of the stomach, duodenum and jejunum. By accident and observation have the great discoveries of x-ray, insulin and penicillin been found. So, too, we have found by sectioning the sphincter of Oddi to cure biliary dyskinesia and to prevent recurrence of gallstones—in the common duct, the release of pancreatic juice cured duodenal ulcers in 3 of our patients who were suffering from both lesions, and 1 of our patients had an anastomotic ulcer. This work is confirmed by the findings of the Mayo research staff. The Mann-Williamson operation on dogs proved that peptic ulcers occurred down to the entrance of pancreatic juice into the intestine. Likewise, in the Whipple operation, in which the stump of the pancreas, with the shortened duct of Wirsung, is anastomosed to the jejunum, there is not recorded in the literature a single case of peptic ulcer occurring at this site, where pancreatic juice enters the small intestine. Peptic ulcers will not occur and will invariably heal in the presence of pancreatic juice. Treat peptic ulcers with nature's alkaline pancreatic juice.

Dr. Russell S. Boles, Philadelphia: We have passed through the eras of gastroenterostomy and the various stages of gastric resection, both for gastric and duodenal ulcer, only to be disillusioned, except possibly in the case of resection for gastric ulcer. The local results from the latter are good. What the systemic results may be still remain to be determined. We are now witnessing the dawn of vagotomy and regretfully must admit there are many clouds on the horizon. First, we would like the gentlemen concerned to make up their minds whether the operation of vagotomy should be done above or below the diaphragm. Anatomic studies by different persons do not agree on which should be the best approach. There is something wrong somewhere in this picture. Gastroenterostomy is now being advised as a supplementary operation to vagotomy. I cannot understand by what magic all the previous hazards of gastroenterostomy will suddenly be dissolved by doing a vagotomy. Certainly it will not be because either operation produces a state of anacidity. We know now, of course, that anacidity is not achieved by a gastroenterostomy, though such was the original intention of the operation, and there is already sufficient evidence that in most cases even vagotomy is not likely to effect a permanent state of anacidity. What then is to be expected from gastroenterostomy under these circumstances? I can only foresee all the direful things that happened previously and that dictated the abandonment of this operation. If vagotomy is being done to reduce acidity, it would be interesting to know how one is going to explain the logic of deliberately reducing pancreatic secretion, which we have been told vagotomy does do, when this secretion is one of nature's most effective means of neutralizing excess acidity. I would suggest that surgeons declare a moratorium on vagotomy for a five year period. There have been more than enough of these operations done by now to serve for follow-up study to determine just how valuable the operation may be. I must express disappointment in the emphasis given to the old theme song "No acid, no ulcer." I do hope that eventually we will develop a little more breadth of vision about the etiology of ulcer. For fifty years we have been approaching ulcer, medically and surgically, on the assumption that it is caused by acid. Surgeons and physicians alike cannot say that they have achieved any real permanent cure for ulcer on this basis. As long as we have not solved the problem of ulcer in the past fifty years by this method of approach, it does seem time that some new aspects of it should be more seriously considered.

Dr. Richard Lewisohn, New York: Many members of this audience will remember the battle which centered around partial gastrectomy versus gastroenterostomy in the treatment of duodenal ulcers about twenty years ago. It took many years to settle this controversy in favor of gastric resection. Dr. Dragstedt has reopened the question of the surgical treatment of peptic ulcer by attacking the vagus nerve transthoracically, or, more recently, transperitoneally. Dr. Dragstedt deserves great credit for his careful experimental work which led him to use vagotomy in patients. Just as Blalock and Taussig did extensive work on animals before they introduced their new methods into clinical surgery, Dragstedt prepared himself thoroughly before he attempted vagotomy in patients. We should reserve final decision of the value of Dragstedt's operations for two reasons: One, vagotomy is followed in many cases by marked interference with gastrointestinal motility, and secondly, follow-ups seem to indicate that free acid in the fasting contents is still present in the stomach in a considerable number of cases, thus opening the door to persistence or recurrence of ulcers. Pronounced atony, sometimes extending over many weeks, is observed in many cases. I have always considered pronounced atony as one of the most dangerous complications following abdominal operations. This postoperative complication should not be taken lightly. Postoperative anacidity is the best safeguard against recurrent ulcer. For this reason, the follow-up results of subtotal gastrectomy for gastric ulcer are perfect. However, in many cases of gastric resection for duodenal ulcer, free acid is still present not only immediately after the operation but in late follow-ups. In this latter group the incidence of recurrent ulcer is about six per cent. If vagotomy would establish a permanent postoperative anacidity in every case, this new operation would be on much safer ground. However, that does not seem to be the case. For this reason I should like to warn against combining vagotomy with gastroenterostomy. It has been stated that gastroenterostomy is a disease, not an operation. I wonder whether vagotomy plus gastroenterostomy will give better end results than simple gastroenterostomy and will prevent the occurrence of gastrojejunal ulcers. It may not be advisable to combine vagotomy with partial gastrectomy for duodenal ulcer, as the atony may represent a serious postoperative complication. However, in a small group of recurrent ulcers following gastric resection a transthoracic or transperitoneal vagotomy may represent a good method.

Dr. Waltman Walters, Rochester, Minn.: The completeness of my method is demonstrated by a motion picture which was shown a number of times at sectional meetings of the American College of Surgeons the past year. Moreover, microscopic examination of the resected portion of tissue should be made to confirm that it is nerve tissue. In most of my cases there have been two distinct nerves, in a few three and in some four. In about 8 or 10 per cent, multiple branches were disclosed in the anatomic dissections. I cannot refrain from commenting on Dr. Boles' discussion because I think we should not forget that in most instances the patients with duodenal ulcer who are referred by the internists to the surgeon for operation are those who have not responded adequately to a medical regimen and who must have relief from either pain, obstruction or hemorrhage. These patients make up that group in which surgical procedures have been carried out by my colleagues and myself and, in those cases as well as similar cases in which other surgeons operated, as has been shown in thousands of instances, definite results have been recorded after the operation of partial gastrectomy, and the results have generally been very good. We should not overlook that fact, because to those patients such an operation, which is now performed with such a low mortality rate by all surgeons of experience is really a life-saving measure. We must not forget, either, that the operation of partial gastrectomy in the treatment of chronic, recurring gastric ulcer that has not responded to a medical regimen has given some of the best results of any method of therapy. The risk is low and recurrence may never take place, I have, myself, never seen recurrence of an ulcer in cases in which resection has been done for a gastric ulcer alone and in which the pylorus has been removed with at least half of the stomach and the ulcer. We should remember that only about 2 per cent of patients get recurring ulcer after partial gastrectomy for duodenal ulcer, and practically never is there a recurrence when the operation is performed for gastric ulcer. But in the 2 per cent of patients who have recurrences of duodenal ulcer after partial gastrectomy, vagotomy will frequently cause healing of the ulcers. Dr. Dragstedt's studies are fine contributions to the surgery of recurring ulceration. Differences of opinion are a healthy thing. However, we must be sure that we are talking about similar groups of cases, that the lesion exists, that a complete division of the vagus nerve is made and that an accurate follow-up is carried out.

ALLERGY FROM THE PERSPECTIVE OF GENERAL MEDICAL PRACTICE

HARRY L. ALEXANDER, M.D.
St. Louis

Clinical allergy has been recognized for thirty years. Before then asthma, hay fever, urticaria and eczema were considered somehow related, but the demonstration that all these were manifestations of a single underlying disorder, then called "protein sensitization" or "anaphylaxis," was an advance in medical progress. Not only was this type of human hypersensitiveness demonstrated by means of a positive reaction to a cutaneous test but this test presumably indicated the actual substance, such as a particular food, pollen or animal dander, that caused the symptoms of which the patient complained. This dramatic revelation soon took hold on medical imagination.

During the first fifteen years the cutaneous test was the keystone to the practice of allergy Many hundreds of allergens were found to produce positive reactions, and there was continual search for new ones. Foods, plants, hair from native and wild animals and bacteria were extracted in increasing numbers until as many as seven hundred tests were given to some patients whose only complaint may have been nasal stuffiness or urticaria.

The process of manufacture of these allergens and their application was time consuming and required particular knowledge and technics so that before long allergy became a specialty. Its immunologic aspects invited research, from which important discoveries evolved. Like other specialties, the study of allergy drew away from general medicine. A phraseology of its own was developed, with such words as "atopy," "atopic reagin," "skin sensitizing antibody," "thermostable antibody" and others.

During this developmental stage there were two guiding principles. One was an implicit reliance on the cutaneous test, although doubts were expressed early, and the second was that if a patient reacted positively to the test the substance responsible for it was the cause of his symptoms and was removed completely, whenever possible, from his environment. The first principle is understandable, for the tuberculin test of the skin was known to indicate the presence of tuberculosis of the lungs and other organs. As a matter of fact, the similarity of the two phenomena of hypersensitiveness led to the adoption of the term "allergy" for both.

If a patient reacts positively to a cutaneous test with one allergen, he is apt to react to tests with many. The application of the second principle, namely, that each of these substances should be excluded absolutely from his environment, tended to produce difficulties. Such measures as omitting a large number of essential foods to the point of undernutrition, discarding overcoats, sweaters, blankets and rugs and even removal of overstuffed furniture from the house if a positive reaction to feathers appeared on the skin were not uncommon practice. These measures were supplemented by injections of mixtures of many allergens in the hope of rendering the patient less sensitive. Unfortunately, such treatment was too often unsuccessful, and then it became an absurdity in the opinion of referring physicians, who also were not sufficiently successful in treating their patients on the basis of positive reactions to cutaneous tests with allergens then on the market. To be sure, many patients did well, but it was the extreme measures then in vogue that made allergy unpopular, and from the perspective of general medical practice it reached a low ebb.

During the last fifteen years a more rational viewpoint has developed. Fallibilities in interpretation of cutaneous reactions became recognized and their proper evaluation formulated. Moreover, a guiding principle became emphasized, namely, that for symptoms to occur there must be sufficient contact with the offending allergen as well as adequate absorption of it. This led to the corollary that patients who have symptoms frequently or continually, and these are the ones who seek medical attention most, must be exposed to some common allergen in their environment. As a matter of practice, it has been found that there are not many allergens in the ordinary surroundings that cause frequent symptoms. It is a statistical fact that feathers, dust, house pets, milk, wheat and a few others are responsible for many cases. Some occupational environments, such as barns and bakeries, present particular problems, but these as a rule are more obvious than obscure. There may or may not be a correlation between the allergens to which a patient is clinically sensitive and positive reactions of the skin.

Emphasis on the fact that most continual symptoms of allergic asthma are due as a rule to comparatively few allergens is having a definite influence on the practice of allergy. In the first place, standardized and approved lists of allergens for routine testing of the skin have been reduced from many hundreds to dozens. Of more significance is the emphasis on the elicitation of a proper history, which includes environmental and dietary factors and differential diagnosis, rather than on cutaneous testing. This alone often reveals the clue to the cause of trouble.

More and more, general practitioners and specialists are becoming aware of this emphasis. Physicians in increasing numbers are taking courses in allergy, and the sale of books on allergy never was so great. A careful elicitation of the history, knowledge of allergens, the correct performance and interpretation of a limited number of cutaneous tests, the proper way of giving injections for hay fever, the risks involved and the manner of creating a dust-free environment and elimination diets comprise the measures with which allergy is now being combated by an increasing number of physicians.

To be sure, a concentrated course for a week or two by no means equips one to practice allergy, but it does teach the essentials. It provides sufficient knowledge to indicate which problems are difficult and which are simple and may respond to the proper application of fundamental principles. Unfortunately, many physicians attempt to practice allergy even without this limited information, but aside from that situation and from the question of how much training one should have there is no doubt that whereas in the earlier years allergy was treated largely by allergists now it is becoming more and more integrated into the general practice of medicine. This differs in no way from experience in the field of cardiology, gastroenterology and other specialties.

At the present time the laity and many members of the medical profession still believe that allergy accounts

Read before the Section on Miscellaneous Topics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

for many more of the ills of the flesh than it really does. Part of this belief is traditional, and part is due to the appearance of books and articles, written in good faith, in which allergy is held responsible for a large number of disorders of various systems of the body and the allergic person is alleged to be beset on all sides by harmful allergens in his food and environment and is warned that contact with even a minute amount of these may be his downfall. Since this is not correct, an evaluation of the true status of clinical allergy and of what can and cannot be accomplished by treatment must eventually be made.

One of the few advances in clinical allergy has been the realization that many cases of intractable asthma, urticaria and vasomotor rhinitis, especially those in which the trouble begins after the third decade of life are different from typical cases of hypersensitiveness to environmental allergens. In the former cases evidence of such hypersensitiveness is lacking. Infection plays an important etiologic role in some cases, but it remains debatable whether true bacterial allergy exists in such instances. In others the cause is unknown, and since no evident extrinsic or environmental circumstances are apparent, these have been designated as cases of "intrinsic" allergy since there is no direct approach in terms of removal of offending allergens or "desensitizing." These are the severe intractable cases, sometimes with serious complications, and in asthma deaths occur mostly among patients with this condition. It is such patients who are eventually referred to the allergist, but unfortunately since there is no specific treatment they are subjected to the process of trial and error and treatment is symptomatic and far from satisfactory.

Despite a large amount of literature on clinical allergy, little of consequence has been discovered in the last decade. The recognition of "intrinsic" causes, still unaccepted by many, and the advent of antihistaminic drugs are the more important advances. This does not hold true for some experimental aspects of allergy or important discoveries that have clinical bearing made by pathologists and immunochemists, to be spoken of presently.

Clinical allergy is at a fork in the road. One branch is a continuation of present practice, which is largely a matter of routine procedures with a high degree of specialization and a tendency to withdraw farther away from internal medicine. There is on the other hand a growing recognition that this specialty as now practiced is but a relatively small part of the field of allergy although it is important since it deals with a large number of afflicted persons and methods of successful treatment. However allergy has far wider implications than this.

Bacterial allergy, not as it concerns asthma but with respect to its role in rheumatic fever as well as its role in tuberculosis, brucellosis and other infectious diseases, is of significance.[1] The importance of hypersensitiveness to simple chemical substances is coming to be realized and has wide application not only in contact dermatitis but in drug allergy. As man is becoming exposed to an expanding list of chemical agents hypersensitiveness to these is increasing. Knowledge of the underlying mechanism involved is being unfolded by immunochemists.[2] Moreover, the suggestive revelation that toxic and allergic tissue reactions to sulfonamide compounds and possibly to other drugs are all of the same nature, as interpreted by pathologists, increases the importance of drug allergy.[3] The correlation of a triad of symptoms of serum sickness, namely, fever, urticaria or purpura and arthralgia, with the same triad of symptoms in rheumatic fever, some drug allergies and allergic purpura is attracting attention, and abroad a relationship has been found also with periarteritis nodosa and lupus erythematosus. Vascular allergy as demonstrated by periarteritis nodosa and by the experimental production of the lesions of this disease and of the Aschoff bodies of rheumatic fever in the same rabbit after sensitization with horse serum has introduced a new and provocative clinical concept.[4]

It is encouraging that these allergies are now appearing on the programs of meetings of allergists, internists and pathologists and are attracting increasing attention A few allergists have begun to engage in research on them. However, the great majority of allergists still are concerned largely with conventional and specialized technics. The more specialized these become the farther they are separated from the essential implications of internal medicine.

The scope of allergy requires a broad knowledge of medicine, which has led to the requisite imposed by recognized boards that in order to specialize in allergy one must first be certified for the practice of internal medicine or pediatrics. This rule has met with protest. Moreover, if a younger man wishes to specialize in allergy today and be certified by accepted subspecialty boards, he must fulfil rigid requirements. Certainly, if one is to become concerned with the newer aspects of allergy as well as with the conventional ones, he must have a prepared mind since so much is involved.

The future progress of the study of allergy lies in attracting the interest of such men away from the restricted applications of this specialty to the broader ones, as well as in increasing the interest of physicians in many fields of medicine. This should draw allergy closer to general medical practice and lift it to a higher level.

ABSTRACT OF DISCUSSION

Dr. Stearns S. Bullen, Rochester, N. Y.: Every physician, whether his interests are limited to a special field or whether he works with general medical conditions, must be concerned with the problems of allergy, because major allergic diseases occur in 7 to 10 per cent of the population. They affect all age groups, they tend to recur over periods of years, they affect many organ systems and, although the covering and lining membranes, that is, the skin and the mucous membranes of the respiratory and digestive tracts, bear the brunt of the reaction, the functions of the circulatory and nervous systems are usually disturbed. The implications of the increasing incidence of sensitivity to such chemical compounds as the new synthetic drugs and the plastics used in industry cannot be overlooked. Fortunately, one or more specific causes can be found in a large proportion of cases by means of an adequate history and appropriate tests of the skin or mucous membranes. A knowledge of the natural course of the disease and of the variations which occur in different circumstances is a requisite for the history taker. He must be prepared to spend sufficient time to get a detailed account of the patient's environment and habits. He requires a working knowledge of the distribution of the substances which the history may indicate are offending factors. This may involve acquaintance with the use of such diverse materials as those handled in a beauty parlor or the type of glue used on a wooden airplane wing. It is pleasing to hear a careful clinician like Dr Alexander emphasize that a few dozen properly chosen and properly evaluated skin tests will give adequate information in most cases. With every positive test it is necessary to determine whether contact with this substance seems adequate to explain the symptoms and whether the patient comes in contact with this substance. The allergic patient is not exempt from disease due to causes other than allergy and is entitled to study from a broad medical viewpoint.

PHYSICAL FITNESS

Report of the Subcommittee of the Baruch Committee on Physical Medicine

ROBERT C. DARLING, M.D., Chairman
LUDWIG W. EICHNA, M.D.
New York
CLARK W. HEATH, M.D.
Boston
and
HAROLD G. WOLFF, M.D.
New York

A clear definition of the term physical fitness is elusive. Physical fitness in the broader sense with which the physician is concerned has no meaning unless ualified "for what." The purely physical requirements f various tasks, whether they be jobs or physical feats, are too varied to be determinable by any one set of criteria. Physical fitness should be discussed as a fundamental quality of a person which describes the satisfactory integration of his muscular, cardiovascular and nervous systems and could be evaluated separately by appropriate tests from the psychologic and emotional factors which modify his actions. This distinction between physical fitness, which is a simple physiologic attribute, and the more general fitness which is affected by the complexities of the personality and its environment is impractical and usually impossible with the knowledge and test methods available at present. Therefore, the term physical fitness as used in this report has a broader meaning than that frequently used and includes the variety of factors which affect human performance. Many instances can be cited in the army and in civilian life of persons well endowed physically who could not carry on practical tasks because of the emotional and psychologic elements involved. Likewise, there are many persons with poor physical equipment and even anatomic defects who, judged by accomplishments, are fit to carry on their jobs. The only final test of fitness seems to be the ability to perform the task desired without undue fatigue or exhaustion, and the qualities making this possible are those of the total personality.

The wide connotations and lack of definition of the unqualified term physical fitness are emphasized if one considers the groups of persons for whom it may be desirable to estimate physical fitness. We may list the following seven broad groups, no one of which, however, is simple and homogeneous (these are but examples; one could add infants and children, and other groups will come to mind):

1. Athletes, persons of school and college age and soldiers and sailors in training, considered as athletically occupied. Various degrees and kinds of fitness for different sports may require emphasis on differing aspects of physical fitness even in this sphere.
2. Laborers, including those factory workers, farmers and miners who are required to do strenuous physical tasks.
3. Sedentary workers, including the white collar class, professional groups, business executives and supervisory factory workers.
4. Workers in specialized duties, such as airplane pilots, policemen, locomotive engineers, submarine personnel and other specialized personnel of the armed forces.
5. The functionally handicapped (otherwise healthy). Here would be included the orthopedically handicapped and special subgroups such as the blind, the deaf and the mentally deficient.
6. Convalescents, which might include both those recovering from acute self-limited infections and those with more chronic debilitating diseases.
7. The aged, including those suffering from changes attributable to age, without specific disease.

The first four of these groups contain those who are presumably well and healthy; the last three groups concern those that present more distinctly medical problems.

Even in the limited fields of athletic fitness and fitness for hard muscular work the picture presented by previous workers is not simple. The following list is of the four main aspects of fitness emphasized in this group. A similar approach to the subject should preface the study of fitness for any task.

1. General cardiorespiratory, vascular and neuromuscular fitness: This concerns the ability to perform work requiring the more strenuous use of large muscle groups and placing stress on the heart and lungs, the blood supply to the muscles and the internal economy of the body.
2. Skill and agility: This involves the smooth integration of the neuromuscular system for either delicate or gross tasks. In part, it is an inborn characteristic; in part, it is the result of past experience. All tasks require some degree of this quality. It includes not only skill in an accustomed task but also rapid adaptability to new tasks.
3. Special strengths: Actual physical strength for specific tasks. The stoutness or mass as well as quality of bone, muscle and joint here come into consideration.
4. "Motivation": By this we mean the goal which a man seeks consciously or unconsciously by his efforts, his "will to do" and "will to succeed." It is so intimately linked with physical fitness, however classified, that it should be considered in any investigation of physical fitness.

These four subdivisions present only a sketchy outline of the aspects of athletic fitness. Different aspects of fitness are brought out by exercise of short, moderate or long duration, although endurance to severe exercise of several minutes' duration and that to more moderate

Taylor, Ph.D., Associate Professor, Department of Engineering, University of California, Los Angeles, and Augustus Thorndike, M.D., Boston.

exercise of long duration, such as mountain climbing, have great similarity. However, the ability to expend a single sudden burst of energy would appear to involve different processes than those exercises leading to gradual exhaustion. Resistance to fatigue has not been mentioned in these subdivisions since it comes in all. The factors leading to fatigue and the "breaking point" are nonetheless important and worthy of separate consideration. Likewise, the study of physical constitution and body build enter into the four aspects mentioned.

The subdivision motivation, although placed last in the list, might well be considered first in most practical situations, especially in the interpretation of laboratory tests. Universal experience has been that the physical could not be adequately dissociated from the psychologic aspects. In fact, the outcome of even simple and rather artificial tests of physical performance is often determined by various psychologic factors lumped together under the term "motivation." Of course, motivation is often quite different in a test situation than in the tasks of daily life.

Aside from the strong and often unpredictable psychologic factors involved, there are at least two other elements about which we know little which make the establishment of universal standards for fitness hazardous. The first is the influence of age and sex on the physical equipment of a person. The tests of "athletic" physical fitness applied to large numbers of persons have been for the most part on young persons, chiefly men. As will be indicated later, more information is needed about the exercise physiology of older persons in spite of the excellent start in the work of Robinson.[1] The second influence against universal standards of fitness is the large number of persons with physical defects who cannot be judged by fixed standards but who, we know, can often carry on an active and useful life, and so by that ultimate criterion can be considered fit.

In summary, then, physical fitness is a complex concept difficult to define and more difficult to measure but one which in its most useful form must evaluate the total individual. This became apparent even in such relatively homogeneous groups as the army; it is accentuated to the physician who must deal with the general population, a heterogeneous group consisting as it does of persons of both sexes, all ages, varying physical endowments and diverse psychologic environments. It seemed advisable, therefore, to point out at the outset some of the weaknesses of certain proposed concepts of physical fitness and of tests to measure it and to emphasize the inadvisability of attempting to set up universal standards. In our opinion the dangers of the oversimplification of the concept of fitness and the misapplication of simplified fitness tests are great. Moreover, it is unwise, and indeed impossible, to define standards of physical fitness at the present time. These negative conclusions by no means invalidate the concept of physical fitness; rather they serve the useful purpose of indicating just where knowledge of the subject stands, thus preventing conclusions on false premises.

In place of simple tests and standards we offer general principles which outline the methods by means of which a useful approach can be made toward the appraisal of physical fitness. Most of the methods are those which the physician already uses, consciously or unconsciously. The emphasis is on the dynamic or functional rather than the anatomic or static. As knowledge advances, the principles which underlie the functionally sound body and well adapted person will become clearer even though at present they can be stated only as generalities.

THE ORTHODOX MEDICAL EXAMINATION

The purpose of the usual medical examination is to discover organic physical defects. It is highly desirable, however, to extend the scope of the physical examination. In relationship to fitness it is necessary not merely to discover defects but to consider the potential performance of the patient in spite of his defects. For example, defective sight or hearing, especially if helped by glasses or hearing aids, may be no handicap to daily life. Good insight and strong motivation on the part of the patient can overcome even severe handicaps. In general one may say that organic disease and abnormalities affect fitness only when they reduce physical and mental activity below that necessary for the effective carrying on of the patient's job or when they reduce the prospect of continued life. Again the emphasis is on the dynamic state of the individual, rather than on the anatomic aspects of illness.

The routine medical history and physical examination can and should do more than assess physical defects. As has been seen, the ultimate test of fitness is the ability to perform the required tasks of daily living. Thus the medical history should include the reactions of the patient to his daily activities. Chronic or cumulative fatigue, diminution in effective work and excessive absenteeism from the job are all evidence of unfitness, and if no organic cause is found, search for social or personal factors may reveal the cause.

FUNCTIONAL TESTS AS AN ADJUNCT TO PHYSICAL EXAMINATION

Although simple forms of exercise are used by most physicians as part of the physical examination to assess the cardiovascular system, it should be profitable to extend this form of examination to learn more about the physiologic state of the individual as it may bear on fitness. No single form of exercise test can be suggested for this evaluation, but some of the rules established by physiologists in the study of homogeneous groups may be mentioned as a guide.[2] It should be mentioned again that the performance on any test involving general exercise is the sum of the patient's cardiovascular-muscular equipment, plus his desire and willingness to try hard. Actually, the psychologic drive, the will to do, should be considered a part of fitness. The difficulty with this component of fitness is that it may play an altogether different role in the test than in daily tasks or emergencies, and therefore escape evaluation.

The physician is often ill trained to evaluate the dynamic state of the subject. Such training should begin early in medical school. Along this line Landis[3] has reported a reorganization of his laboratory course in physiology, which should give better emphasis to man as an integrated organism, reacting to various stress conditions. The same approach might well be incorporated in other medical school departments so that the physician will come to consider the patient as a whole in relationship to the various internal and external stress factors. Obviously the technics for making this evaluation are often lacking, but unless at least the point of view is acquired early in a physician's career, progress will be slow in his ability to evaluate functional health, which is practically a synonym for "fitness."

[3] Landis, E. M.: Physiology for Medical Students at Harvard, Harvard M. Alumni Bull. **19**: 9, 1944.

Workers in the field of exercise physiology agree that the physiologically efficient subject will show the following manifestations during and after a bout of strenuous exercise:

1. Ability to work at a high metabolic rate without undue disturbance of the cardiovascular system. At the same time the ability to increase cardiovascular work to very high levels before exhaustion.
2. Ability to continue to maintain a high metabolic rate.
3. Prompt return of the cardiovascular system toward the resting state after stopping exercise.
4. Postexercise well-being and the ability to continue usual activity.
5. Adequate vasomotor response both when rested and after exercise.

Although the basis for these statements is the study of healthy young men, it is generally and probably correctly assumed that the same manifestations, graded downward on a sliding scale of physical work, may also apply to healthy man as he ages or as he convalesces from an illness.

Test exercises to assess the capabilities of the cardiovascular-muscular system should be severe enough to place considerable stress on the subject, and should involve a type of exercise using large groups of muscles and requiring a minimum of skill. It is generally agreed that several test exercises are preferable to one.

The rules for test exercise as an adjunct to the usual physical examination cannot be made more specific in our present state of knowledge. It is believed that these principles hold in patients with loss of part of their muscular apparatus as in paralysis, for here one tests the function of that which remains, but of course special exercises must be devised for persons suffering particular defects. Tests that apply to practical work situations are to be recommended.[4] The efficient working of the circulatory and muscular apparatus can be considered an attribute of part of a man as well as a whole man. This attribute must be present sufficient for the patient to carry on his daily work and pleasure, and probably enough more to meet emergency needs, before he can be considered physically fit. The converse is not true; he may have an efficient body but not use it to carry on ultimate tasks by which one may judge him fit.

The physician can attempt to evaluate the first four points from observing the patient during and after exercise. The fifth point, concerning vasomotor response, is not seen directly from response to severe exercise. Since some manifestation of vasomotor stability and prompt adaptability have been the basis of many of the proposed tests of physical fitness, it is important to consider them. Among normal young men it has been common experience that vasomotor adaptability does not necessarily parallel performance ability in strenuous tasks. Therefore it is probably wise to consider performance ability and vasomotor adjustment as dissociated manifestations of a well functioning body. The advantage to the individual of a vasomotor system which adjusts readily to change in posture, heat and other stress conditions is self evident. Some method of evaluating it should be part of the physician's total assessment of the patient, whether it be the response of the patient's pulse and blood pressure to the excitement of a visit to the physician or a more elaborate test.

PSYCHOLOGIC EVALUATION

As was indicated early in this report the physical equipment of the patient and his physiologic response to stress are only a partial though necessary component of fitness. The final test is how he uses his equipment in his play and work. Although the judgment of the total individual, his will to do, his "motivation" and the factors behind it, may be said to be in the realm of psychiatry, many and perhaps most cases can be properly assessed by the discerning physician without special training. His approach need not involve highly specialized technics but will require an orderly evaluation of the patient from his history, his conversation, his general attitude and purposes in life, his reactions to simple situations (such as his reactions to the physical examination). The technics of evaluation by interview used by psychologists, personnel workers and others might be utilized with profit by the physician.[5] The best judgment will most often come from frequent contact when the patient is seen "as he is" in his work and under the stresses of his daily life.

Undoubtedly some psychologic situations are too complex to be approached by the physician without special training. In these cases the psychiatrist is essential as a consultant. In all situations requiring evaluation of personality the psychiatrist would be helpful, but it is obviously impossible to require a full psychiatric work-up for each judgment of fitness.

This discussion would not be complete without at least mention of the probable significance of fitness to the individual. It would appear that the chief objective of the attainment of physical fitness is to bring a person to that state whereby he can perform those tasks which will permit him to become an active member of society, economically independent if necessary. Moreover, he should be able to perform the tasks repeatedly without fatigue and have in addition a reserve to meet and sustain unexpected stresses, should they arise, without being incapacitated by them. A physically fit person will be able to meet these requirements and still maintain a sense of well-being. This picture of functional health is certainly an adequate goal. Actually there are no satisfactory data to predict that the physically fit subject will have a longer life span, a lower incidence of degenerative disease or a greater resistance to infection than his unfit confrere, although these relationships might well be studied further. However, in the psychologic and sociologic spheres various other possible benefits of fitness should be recognized, such as the aesthetic gains so often evident in body building or the frequently desirable personal discipline necessary for physical development.

Functional health cannot be attained by physical fitness alone, narrowly considered as a problem of the soma. To make judgments of physical fitness for the attainment of functional health and all that this may mean for the individual, one must include the study of the personality in a broad sense, distinguishing, if possible, the more constitutional patterns from what are more the product of environmental and cultural forces. Indeed, one may have to consider cultural patterns of family, race, religion and those of the age or time. The concept is thus a large one, impinging on many branches of the medical sciences and allied fields in the study of man.

SUMMARY

Physical fitness describes the functional capacity of the individual for a task. It has no real meaning unless the task or job for which fitness is to be judged is specified. The fit individual can perform the task repeatedly without undue fatigue and has a reserve capacity to meet and sustain unexpected stresses which may arise. Because of the complexity of the concept and the wide variety of tasks carried on by different persons, universal standards for its evaluation are not feasible. Their establishment in any form would be a misleading oversimplification.

Physical fitness for a task depends on the physical equipment and physiologic competence of the subject for the stress which the task imposes, together with the complex psychologic factors grouped under the term "motivation." The physical and psychologic factors cannot be fully dissociated even in test procedures.

Since physical fitness involves more particularly a functional concept rather than an anatomic one, it is important that the physician be able to evaluate the functional capacity of his patient, whenever possible, by appropriate tests of working capacity and vasomotor response.

Since physical fitness is often governed by psychologic factors which overshadow the physical competence of the body, it is important for the physician to evaluate the total individual, with the help of the psychiatrist when necessary.

There is need for more data on physical capacity and physiologic adjustment in respect to age and sex factors, specific work situations in different environments, skills, strength and learning abilities in order to furnish guides to the physician in his judgment of a functionally normal body.

Clinical Notes, Suggestions and New Instruments

A MODIFICATION OF THE CROSBY-COONEY OPERATION FOR INTRACTABLE ASCITES DUE TO CIRRHOSIS OF THE LIVER

JERE W. LORD Jr., M.D.
New York

In 1946 Crosby and Cooney[1] revived interest in an operative procedure for the treatment of intractable ascites and reported several cases in which considerable improvement was obtained following operation. The procedure which they described had been employed from time to time for several decades but for a number of reasons had never become popular. They eliminated one of the difficulties by employing a glass button with a cap on it to prevent plugging of the lumen by omentum.

The principle underlying the operation is the transport of ascitic fluid from the peritoneal cavity through a glass button to a subcutaneous pocket where it can be absorbed by the lymphatics. When the operation is successful, the patient is spared the unpleasantness of and repeated need for paracenteses and, secondly, has in a sense a slow constant clysis of a fluid which may contain a significant amount of protein. In some patients the loss of protein due to repeated paracenteses may be considerable.

In January 1947 I saw in consultation a patient with advanced cirrhosis of the liver and an uncontrollable wasting ascites. He had been subjected to the Crosby-Cooney operation approximately three months earlier and for a period of two months had obtained almost complete relief from his ascites. However, after two months the subcutaneous pocket stopped absorbing fluid and the ascites reaccumulated rapidly, necessitating resumption of paracenteses. The man was unfortunately too ill to contemplate a portacaval anastomosis.[2]

When this case was discussed with Dr. Irving S. Wright, he pointed out that operations for chronic lymphedema of the legs by the Kondoleon procedure or one of its modifications are most effective when the deep fascia is removed along with the edematous fat, thereby exposing the lymphatics of the muscles. With this suggestion in mind, on March 20, 1947, I carried out the Crosby-Cooney operation on a 55 year old Chinese man, but in addition to their technic removed approximately a 6 by 6 inch (15.2 cm.) layer of fascia, thereby exposing portions of the following muscles: the internal oblique, the right rectus and transverse abdominal muscles. Also Scarpa's fascia was excised to expose the fat superficially. Sufficient fascia was left for the closure of the mid right rectus incision and for the stability of the button.

REPORT OF CASE

T. T., a 55 year old Chinese man, was admitted to the Gouverneur Hospital[3] on Sept. 19, 1946. Because of language difficulty the only facts obtained were that the patient had had a swollen abdomen and a painful umbilical hernia for some time. Physical examination revealed an alert, emaciated man of stated age with decided abdominal distension, prominent periumbilical veins, a large thin-walled umbilical hernia and evidence of a large amount of ascitic fluid. The spleen could not be palpated but the edge of the liver extended 2 to 3 fingerbreadths below the costal margin. The heart showed an auricular fibrillation which was confirmed by an electrocardiogram. The lungs were clear although the diaphragms were considerably elevated. There was no peripheral edema. Laboratory studies showed the following: The urine was normal, the serum protein was 6.5 Gm. per hundred cubic centimeters, with the albumin 2.8 Gm. and globulin 3.7 Gm; the cephalin flocculation reading was 4 plus; the icterus index was 18; cholesterol was 75 mg. and 66 mg. with esters of 10 mg. and 41 mg. on two occasions; nonprotein nitrogen was 43 mg. per hundred cubic centimeters; the Wassermann reaction was negative; an esophagram showed no varicosities. The hepatic function tests were repeated with essentially the same results on Jan. 20 and Jan. 28, 1947. Also the prothrombin time by Quick's method was nineteen seconds for the patient and the control. Intravenous pyelograms were normal.

Dates and Volumes of Paracenteses

Date	Volume, Cc.	Date	Volume Cc.
10/ 5/46	9,200	1/18/47	6,500
10/11/46	2,500	1/29/47	10,000
10/26/46	7,250	2/ 4/47	8,500
11/20/46	10,000	2/14/47	9,500
12/ 5/46	11,000	2/26/47	4,500
12/16/46	9,500	3/ 7/47	4,000

Course.—The patient was placed on a high protein, high carbohydrate diet with added vitamins, and his general condition improved somewhat. However, it was necessary to perform twelve paracenteses between Oct. 5, 1946 and March 7, 1947 (the table). In February the patient was digitalized without influence on the rate of formation of his ascitic fluid. On March 20, a glass button was inserted in the right lower quadrant and the fascia removed as has been described. At operation 6,000 cc. of clear ascitic fluid was collected. The liver showed a finely granular surface which was frosted with a whitish covering. It was enlarged and hard. The biopsy confirmed the diagnosis of portal cirrhosis of a moderate degree. The spleen was enlarged, being approximately three times normal size. The umbilical hernia, which before operation measured 10 cm. in diameter, had a small internal opening of 1 cm. The patient was allowed out of bed on the following day, and his postoperative course was uneventful. The pocket was full of fluid by the second postoperative day, but of great interest was the fact that scrotal or leg edema never developed as it had in Crosby and Cooney's patients. Further, between the eighteenth and the twenty-ninth postoperative day the fluid in the subcutaneous pocket disappeared; it has since remained completely empty. The umbilical hernia has remained level with the abdominal wall (the figure). When the patient was last examined, five and one-half months postoperatively, he was asymptomatic, able to carry on with his usual activities and was free from demonstrable ascites. The glass button could be palpated easily beneath the skin in the right lower quadrant. Analysis of the serum protein now showed a value of 7.3 Gm. per hundred cubic centimeters with an albumin-globulin ratio of 4.0 to 3.3. The cephalin fluocculation reading was 3 plus.

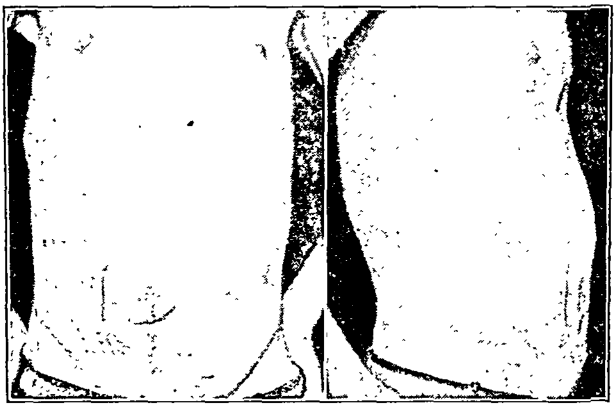
COMMENT

Patients with cirrhosis of the liver and intractable ascites present a real problem to the physician. In spite of the best of modern dietary regimens in some cases of cirrhosis ascitic fluid will continue to collect and require repeated paracenteses. This procedure is both annoying to the patient and not completely without danger of infection. The protein-containing ascitic fluid is lost, and this may be of considerable significance. There are two operative procedures which may help these patients. If there is evidence of esophageal varices and/or a history of massive gastrointestinal hemorrhage and the patient is in good condition then some kind of portacaval shunt should be carried out. However, if ascites is the only problem or if the patient is a poor operative risk, then the Crosby-Cooney button operation with the addition of fascial removal should be utilized. The operation is easy to perform, is considerably less trying on the patient than a portacaval shunt and when successful may bring about complete rehabilitation.



Anterior and lateral views of patient three and one-half months postoperatively. The umbilical hernia is flat and the subcutaneous pocket has disappeared. There is no evidence of ascites.

There unquestionably will be failures with the button operation but in a condition in which high grade invalidism exists, the possibility of helping, by this simple operative procedure, some of these patients with intractable ascites should not be overlooked.

SUMMARY AND CONCLUSIONS

The Crosby-Cooney glass button operation has proved to be worth while in some cases of intractable ascites. In order to facilitate greater absorption of the ascitic fluid from the subcutaneous pocket, a modification of the operation has been made by adding the removal of a large area of fascia with consequent exposure of lymphatics in the muscles. A case is reported which illustrates these points.

ADDENDUM

As a result of one failure in my series and data submitted by another surgeon who had three glass buttons plug with omentum, the following operative details should be employed in addition to the fasciotomy: 1. If an omentum of sufficient length to reach the lower part of the rectus incision is present it should be excised. 2. As much muscle is exposed as is possible through the incision by removing fascia not only lateral to the incision but also across the midline on the opposite side. 3. Great care must be used in closing the skin of the incision to prevent late leakage of ascitic fluid, which occurred in the case cited in this article on the twelfth postoperative day. Subcuticular nonabsorbable sutures are placed followed by end on mattress sutures which are not removed until the fourteenth to sixteenth postoperative days. 4. If ascites accumulates faster than the muscles in the pocket can absorb it, paracenteses should be performed not through the pocket but in the lower quadrant away from the pocket so that leakage will be minimal.

55 East Ninety-Second Street.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

SOLO-PAK HEARING AIDS ACCEPTABLE

Manufacturer: Allen-Howe Electronics Corp., 150 Main Street, Peabody, Mass.

Three Instruments:

Model r, Red Case, Serial 7394, Magnetic Receiver
Model g, Green Case, Serial 7240, Brush Crystal Receiver
Model b, Black Case, Serial 7239, WE 724 Receiver

These three instruments are all assembled on stud-supported insulating sheets and enclosed in cases of a pliable plastic material, without wearing clips. The batteries are self contained, access to battery space being by zipper opening at the bottom of the case. Batteries are changed without removal of the unit from the case. The chassis can be removed from the case through this zipper opening to change cases or to make repairs. The receivers are connected by cord and plug to the chassis, with the cord coming out through a hole at the upper rear of the case.

Volume control (wheel type) is at one side of top of case, and there is a combination on-off tone switch at other side.

Dimensions and Weight

Dimensions: 120 by 51 mm. Weight: 198 Gm. (7 oz.).

Batteries

A battery: mercury, 1.2 volts.
B battery: zinc and carbon, 22.5 volts.

Current Drain Data

	A Battery		B Battery		
				Milliamperes	
Case	Volts	Milliamperes	Volts	Quiet	Squealing
Red	1.2	75	20	0.25	0.30
Green	1.2	50	22	0.30	0.45
Black	1.2	70	21	0.55	0.70

Acoustical Gain

Measurements were made of the acoustical gain in decibels for sound pressure level in a 2 cc. coupler over that pressure level at the microphone placed on the face of a 40 by 20 cm. baffle. The input level at each frequency was 0.02 dyne per square centimeter. Typical results are tabulated as follows (all instruments full on volume):

Frequency	256	512	1,024	1,200	2,250	3,100	4,096
Red case, 1 dot	27	34	41	47	57	34	22
Red case, 2 dots	23	30	38	43	54	32	19
Green case, 2 dots	40	46	60	52	53	32	30
Black case, 2 dots	28	37	43	46	48	33	16

Approximate values of maximum sound pressure levels in the 2 cc. coupler, with volume control set for full gain and tone setting 2 dots, are shown below:

	Red Case		Green Case		Black Case	
Frequency	Input Level	Maximum Output Level	Input Level	Maximum Output Level	Input Level	Maximum Output Level
600 cycles	65 db.	97 db.	65 db.	110 db.	65 db.	103 db.
1,024 cycles	65 db.	102 db.				
2,048 cycles	60 db.	104 db.				
2,250 cycles	55 db.	107 db.				

Intelligibility tests (random words) were made with a person of normal hearing seated inside a booth giving about 30 decibels in sound reduction. The speaking person was outside the booth using a normal tone of voice. These conditions are rather critical, since the signal to noise ratio in the instrument is much worse than that obtained in normal use. Scores made under these conditions are listed below:

Red case	58 per cent
Green case	48 per cent
(Hiss noise masked words badly)	
Black case	68 per cent

At the suggestion of the manufacturer these instruments were dropped from lapel height to a rubber-matted concrete floor and found to operate satisfactorily after several falls. The investigator, weighing 70 Kg., then stood on one of the instruments and caused no damage.

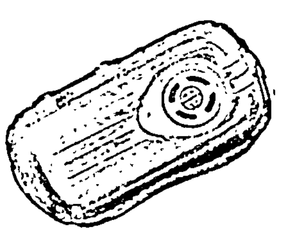
On the recommendation of the Consultants on Audiometers, the Council on Physical Medicine voted to include the three Solo-Pak Hearing Aids in its list of accepted devices.

ELECTRO-EAR HEARING AID MODEL C ACCEPTABLE

Manufacturer: American Earphone Co., Inc., 10 East 43d Street, New York 17.

The Electro-Ear Hearing Aid, Model C, is self contained, the battery compartment being accessible from the back of the case by means of a full length piano-hinged cover. The cream-colored plastic case has a wearing clip secured to the back.

Two wheel-type controls are placed on the instrument. The four position tone control is on the side of the case; the combination on-off switch and continuously variable volume control is centered on the top of the instrument.



Electroncar Model C

The receiver cord has plugs at both ends. Three crystal receivers were supplied for the tests, one large, one small and one special model.

Dimensions and Weight

Weight: 184.2 Gm. (6½ ounces).
Length: 14 cm. (5½ inches).
Thickness: 2.2 cm. (⅞ inch approximately).
Width: 6.6 cm. (2⅝ inches).

Battery Data

Usable batteries: A, 1½ volts; B, 30 volts.

Battery Drain Measurements

	Voltage	Current
A	1.4 volts	47 milliamperes
B (Quiet)	29 volts	1.3 milliamperes
(Squealing)	29 volts	0.9 milliampere

Acoustical Gain

Measurements were made of the gain in decibels in the sound pressure level set up in a coupler over the sound pressure level at the microphone set in the face of an 18 by 8 inch (40 by 20 cm.) baffle. The input level at each frequency was 0.02 dyne per square centimeter. A large crystal receiver was used.

Following are typical results obtained with the volume control full on, at two different settings of the tone control and seven frequencies:

Frequency	256	512	1,024	1,200	2,250	3,100	4,096
Tone Control Setting							
3 black dots	23	29	45	51	38	29	25 decibels
1 red dot	30	34	47	52	46	52	49 decibels

Approximate values of maximum pressure levels, at four frequencies set up in the regular coupler with volume control set for full gain and the 1 red dot tone setting are as follows:

Frequency	Input Level	Maximum Output Level
600 cycles	65 db.	104.5 db.
1,024 cycles	70 db.	113.5 db.
1,200 cycles	70 db.	115.5 db.
2,048 cycles	60 db.	100.0 db.

Zero reference level is 0.0002 dyne per square centimeter.

Intelligibility tests made with a hard of hearing subject gave scores of 85 per cent or better.

The Council on Physical Medicine voted to include the Electro-Ear Hearing Aid, Model C, in its list of accepted devices.

VACTUPHONE HEARING AID MODEL 3 ACCEPTABLE

Manufacturer: Allen-Howe Electronics Corp., 150 Main Street, Peabody, Mass.

This instrument is a plastic-cased hearing aid, using separate batteries. One five-prong plug, fitting into the top of the instrument, has both battery and receiver cords directly connected to it. The crystal receiver supplied is connected to the receiver cord by a plug. The switch is a push-pull type on the top of the instrument. Volume and tone controls are knurled wheel type, one on each side of the unit near the top. A two-directional wearing clip is riveted to the back of the case.

Dimensions and Weight

Dimensions: 95 by 57 by 22 mm.
Weight (including batteries): 266 Gm. (9.4 ounces)

Battery Data

A battery	1.4 volts	85 milliamperes
B battery (Quiet)	29 volts	1.3 milliampere
(Squealing)	29 volts	1.0 milliampere

Acoustical Gain

Measurements were made of the acoustical gain in decibels in the sound pressure level set up in a 2 cc. coupler over that pressure level at the microphone on the face of a 40 by 20 cm. baffle. The input level at each frequency was 0.02 dyne per square centimeter. Typical results are tabulated as follows:

Frequency	256	512	1,024	1,200	2,250	3,100	4,096
Tone low	36	42	58	51	33	33	26
Tone high	39	47	62	57	47	50	43

Approximate values of maximum sound pressure levels, at three frequencies set up in the 2 cc. coupler with volume set for full gain and tone setting high, are shown below:

Frequency	Input Level	Maximum Output Level
600 cycles	65 db.	114 db.
1,024 cycles	65 db.	125 db.
2,048 cycles	65 db.	107 db.

Intelligibility tests (random words) were made with a person of normal hearing seated inside a booth providing about 30 decibels in sound reduction. The speaking person was outside the booth using a normal tone of voice. The score made under these critical conditions was 84 per cent, considered very good.

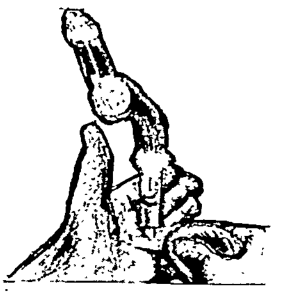
At the suggestion of the manufacturer, this instrument was tested by dropping it from coat lapel level on rubber-matted concrete floor. After three tests it continued to function.

The Council on Physical Medicine voted to include the Vactuphone Hearing Aid, Model 3, in its list of accepted devices.

NEBULIZER NASAL PREMO ACCEPTABLE

Manufacturer: Premo Pharmaceutical Laboratories, Inc., 443 Broadway, New York 13.

The Nebulizer Nasal Premo, like its predecessors, is a device designed to project aqueous solutions as a fine mist or aerosol for inhalation, in this case by way of the nose. It is intended to be used in administering water-soluble, nonvolatile medicaments of high potency, like epinephrine and penicillin, by way of the respiratory tract.



The apparatus is made of glass except for a small metal Venturi tube. The specimen submitted for testing nebulized 1 cc. of water in seven minutes when a hand-operated bulb was used. If compressed air is available, the process can be hastened. Two characteristics of the apparatus are the great fineness of the resulting spray or nebula and the completeness of the process, which latter implies that some control of dosage is achieved.

The Council on Physical Medicine voted to include the Nebulizer Nasal Premo in its list of accepted devices.

SATURDAY, MARCH 13, 1948

NOTICE

At noon Monday, March 8, the composing room staff of the press of the American Medical Association discontinued its work as part of a general disturbance in the printing trade now prevalent in Chicago. The compositors of the newspapers have been away from their work several months. During the past week, discussions between the printers of I.T.U., Local 16, and the Franklin Association, which is the organization of printing establishments, failed to reach any agreement.

The Journal comes somewhat late this week because of the necessity for emergency activities in getting it on the press. Arrangements are in process for publication each week utilizing new printing technics hich are being developed for the purpose.

The Board of Trustees of the Association hopes that subscribers to publications of the Association will make due allowances for difficulties during this period of adjustment.

FOREIGN BODY GRANULOMA

There are two outstanding varieties of foreign body granuloma—one is produced by animate and the other by inanimate material. The foreign substance may be introduced from without, as in injuries, or produced in the body, as in necrotic areas where cholesterol or fatty acid crystals are formed. Occasionally the foreign substance may be inserted in the form of sutures or ligatures in surgical operations or fortuitously as dusting powders on surgeons' rubber gloves, or even deliberately for "beautification."

The tubercle is the most prevalent and familiar example of foreign body granuloma due to a living substance. If, however, as Prudden and Hodenpyle showed many years ago, the tubercle bacillus is killed and dead bacilli are insufflated into the lungs of rabbits, the bacilli produce epithelioid tubercles which are histologically typical except, of course, for the absence of caseation. Nor, obviously, can they reproduce similar lesions locally or in distant tissues. The reaction is due presumably to the insoluble waxy substances with which the tubercle bacillus is provided. In practically all foreign body reactions the histologic picture bears a certain resemblance to the epithelioid tubercle, including the formation of giant cells, the cytoplasm of which is apposed to the foreign body; or, if the foreign body is small enough, it may be included in the cytoplasm of the giant cell and eventually disposed of.

In previous years it was common practice to use dusting powders for surgeons' rubber gloves that contained lycopodium spores. When introduced into the peritoneum and other tissues the spores produced so-called dust nodules, sometimes in sufficient numbers to cause intestinal obstruction and other surgical hazards. In time talc was substituted for lycopodium but likewise produced nodules which are equally dangerous. Nevertheless talc is still being widely employed as a dusting powder for surgeons' rubber gloves in spite of numerous reports of talc granuloma in the peritoneum, rectum, vagina, brain and elsewhere together with a propensity for the powder to convert surgical incisions into sinuses which refuse to heal.

In 1907 Whipple described a disease characterized clinically by gradual loss of weight and strength, by the presence of abundant neutral fat and fatty acids in the stools and by a form of fugitive arthritis. Anatomically, the disease is attended by deposits in the intestinal villi and mesenteric lymph nodes of neutral fats and fatty acids together with extensive infiltration of embryonal fat cells and the presence of variable numbers of multinuclear foreign body giant cells enclosing particles of degenerate fat. Since the appearance of Whipple's paper 7 additional cases have been described,[1] and the disease is now regarded, at least by some pathologists, as one in which degenerate fat cells produce a diffuse foreign body granuloma.

A localized nodular form of foreign body granuloma has been described under the designation of adiponecrosis. This granuloma is due to some sort of injury; such as the infusion of excessive quantities of saline solution into the subcutaneous fat, usually in the region of the breasts. The nodules are composed of mature connective tissue, fibroblasts, embryonal fat cells and giant cells containing remnants of degenerate fat. The lesions may rupture through the skin and give rise to obstinate sinuses.

In a recent report to the New York Pathological Society, Von Glahn and Hall observed a unique form of foreign body granuloma due to cotton fibers in the walls of the smaller pulmonary vessels, the fibers being introduced apparently from gauze filters used in the process of intravenous medication.

There is a form of foreign body granuloma in which giant cells enclose brightly staining, acidophilic, star-shaped bodies that have been variously interpreted as parasitic inclusions, astrospheres, fibrinoid deposits and paraffin or fatty acid crystals. This form of granuloma has been described in various situations, including the tissues of the face following the "beautician's" injection of paraffin for cosmetic purposes. In addition, the beautician is too often responsible for still other foreign body reactions which are not only disfiguring but are ultimate causes of mental perturbation that is even more pronounced than the distress caused by the wrinkles and other blemishes that his injections of paraffin are supposed to remove.

PHYSICAL FITNESS AS PHYSICIANS SEE IT

Elsewhere in this issue is a report on physical fitness by four physicians acting as the Subcommittee on Physical Fitness of the Baruch Committee on Physical Medicine. The report rejects the concept that any one set of criteria can successfully predetermine fitness for the wide variety of tasks and activities of modern life. It also repudiates the idea that fitness can be determined on the basis of physical tests or medical examinations alone. In the words of the report, "The only final test of fitness seems to be the ability to perform the task desired without undue fatigue or exhaustion, and the qualities making this possible are those of the total personality."

Taking athletes as only one of the many broad groups for whom it may be desirable to estimate physical fitness, the report points out that tests in as many aspects as four (general cardiorespiratory, vascular and neuromuscular fitness; skill and agility; special strengths, and "motivation") still provide only a limited idea as to the all-round fitness of the person for athletic participation. The unsolved problem of resistance to fatigue is involved in every one of the foregoing aspects of appraisal.

The Subcommittee believes that it will eventually be possible to evaluate fitness, and it offers, instead of simple tests and standards, some general principles by means of which a useful approach can be made toward the appraisal of physical fitness. Among the general principles set forth, these are outstanding: 1. The orthodox medical examination and medical history should not merely discover defects or diseases but also should "consider the potential performance of the patient in spite of his defects" and "include the reactions of the patient to his daily activities." 2. Several test exercises severe enough to place considerable stress on the subject should be used as an adjunct to the medical examination to assess the capabilities of the cardiovascularmuscular system. (The suggestion is also made that training of medical students in the use of such tests should begin early in medical school.) 3. Through "an orderly evaluation of the patient from his history, his conversation, his general attitude and purposes in life and his reactions to simple situations" the physician should form a judgment as to "the total individual, his will to do, his 'motivation' and the factors behind it." In some cases the help of the psychiatrist may be necessary in this latter evaluation.

Though this report will be disappointing to the physician seeking a simple answer to the problem of evaluating fitness in his patients, the statement merits serious study. In the periodic health examination the emphasis must be placed "on the dynamic state of the individual, rather than on the anatomic aspects of illness." Accomplishment of this proposal will certainly require both time and effort, but the adaptation of functional tests already developed in the field of physical education, and of the interview technics developed by psychologists and personnel workers, might well facilitate the process.

Current Comments

THE ROLE OF ACETIC ACID IN METABOLISM

In the oxidation of various food substances in the animal organism, the various metabolites are probably changed to a common substance and each metabolite is oxidized through this substance in a common pathway. Apparently this is the system operative in animal metabolism; the common substance to which foodstuffs are changed appears to be acetic acid or some closely related compound. Ever since the classic studies of Neubauer, Knoop and Dakin some forty years ago, acetate or some closely related compound has been recognized as a principal intermediate in the metabolism of fat. It now appears[1] that it may also be an intermediate in the final disposition of carbohydrate. Its accumulation may be demonstrated when pyruvate is incubated with slices of tissue in the presence of fluoroacetate, an inhibitor of further oxidation of acetate. The acetate formed in animal metabolism is removed so rapidly in further reactions that its presence in the tissues is detectable with difficulty. The acetate appears to be oxidized principally in the citric acid cycle, a device originally thought to be active only in the oxidation of carbohydrate. It serves also as an important precursor in the formation of cholesterol, the sex hormones, protoporphyrin, purines, acetoacetic acid and the acetyl sulfonamide and acetyl amino compounds. Carbohydrates and fats appear to give rise to slightly different forms of acetate, since the carbon atoms derived from these substances take different positions in the ring of the purine nucleus and also react differently in acetylation reactions. Acetate may also be changed into glycogen, apparently through the reversible reactions which relate carbohydrate to the various acids of the citric acid cycle. The dual role of acetate in both carbohydrate and fat metabolism appears at first sight to be incompatible with present concepts of the ketogenic nature of fat and the antiketogenic nature of carbohydrate. Carbohydrates, it would seem, cannot be antiketogenic if they may be formed from the acetate, the same substance which

---

1. Ploch, K.: The Metabolism of Acetic Acid in Animal Tissues. Physiological Reviews 27: 574 (Oct.) 1947.

forms acetoacetic acid. These concepts may be reconciled only through the realization that there are two different factors involved in the formation of a substance such as carbohydrate. The one factor refers to the amount, as it is usually determined in quantitative analysis; the other refers to "replacement," which may at present be followed only by the use of labeled atoms or isotopes. Acetate formed from fat can replace carbohydrate, but it cannot increase the amount present in the organism because the process by which it is utilized requires the participation of carbohydrate itself. This explains why fatty acid and acetate do not increase glycogen stores in the starved or diabetic animal. Many phases of the role of acetate in tissue metabolism await further investigation. One of the major questions remaining is the exact intermediate form in which acetate undergoes reactions.

FOLIC ACID VERSUS LIVER EXTRACT

Kracke and Riser[1] of the Hematology Clinic, Medical College of Alabama, compared the therapeutic efficiencies of folic acid and liver extract in the treatment of pernicious anemia. In 1945, following Angier's[2] successful synthesis of folic acid, numerous clinical investigators reported its successful therapeutic use in different blood dyscrasias.[3] For comparison of its therapeutic efficiency with that of liver extract, Kracke and Riser selected a group of 4 untreated cases of classic addisonian pernicious anemia in severe relapse. All patients in this group were hospitalized for thorough study. Control observations were made prior to the institution of folic acid therapy. In addition to the usual laboratory procedures, sternal marrow aspirations, complete roentgenologic and fluoroscopic studies of the gastrointestinal tract and gastric analyses were done on each patient. None of the patients exhibited involvement of the central nervous system. A positive hematologic response to folic acid was noted in each case. Following daily oral administration of 20 mg. folic acid, the initial erythrocyte count of 770,000 per cubic millimeter in a typical case was increased to 2,000,000 by the end of twenty days and to nearly 4,000,000 by the forty-fifth day. The initial hemoglobin reading of 3 Gm. was increased to approximately 8 Gm. This seven week treatment was followed by a daily administration of 10 mg. folic acid by mouth. On this reduced dose all patients have been maintained in a state of complete hematologic remission to the date of this report (seven months later) In none of the patients has there developed disease of the central nervous system. Folic acid thus appears to be equally effective with liver extract in the treatment of pernicious anemia. Liver extract certainly contains an active component other than folic acid, since the potency of liver extract is greater than can be accounted for on the basis of its folic acid content. This second antianemic factor in liver extract has not yet been determined.

THERMAL SEDATION

According to experimental evidence recently reported by Cowles and Nelson[1] of the Department of Preventive Medicine, University of California at Los Angeles, a tremendous field awaits study of the effects of altering body temperature on the course of disease, especially when toxic factors are concerned. Their conclusion was based on a study of the effects of low temperatures on the symptoms of tetanus toxin in the desert iguana. This lizard was selected because of its wide range in temperature tolerance and its similarity to mammals with respect to its optimum temperature (36 to 41 C.). In preliminary experiments lizards weighing 65 Gm. were injected intramuscularly in the femoral region with massive doses of tetanus toxin and exposed to normal room temperatures (24 to 26 C.). Thirty-six hours after inoculation the first symptoms appeared as slight tremors in the head and caudal regions. Two hours later action of the hind legs was impaired and the tail was arched strongly in a lateral position. Sound or sudden movements taking place in close proximity to the animals caused convulsions, although fairly periodic spasms were observed without extra stimulation. Prior to death, violent symptoms of tetanic convulsions and opisthotonic contractions threw the animals into strong sigmoid curves with the head inclined upward at a sharp angle. This posture was retained with only slight relaxation after death. In a preliminary test of temperature effects, 9 lizards were divided into three groups, one of which received 100 guinea pig MLD's (minimum lethal doses) of the toxin, another 50 MLD's and the third 5 MLD's. From each of these dosage groups, 1 animal was placed in a heated cabinet at 38 C., 1 in a cage at room temperature (27 C.) and a third in an incubator refrigerator at 10 C. In the group at 38 C. symptoms began to appear in about twenty-four hours, with characteristic convulsive death by the end of two days. With the moderate cooling (27 C.) there was a material prolongation of life, the first symptoms being delayed till the end of three days and death till the seventh or eighth day. With the chilled group (10 C.) no symptoms were noted till the end of the experiment (fourteen days). Tests of larger series of animals and greater standardization of the toxic dose are now in progress. The preliminary tests, however, clearly show that lowering of temperature definitely prolongs life in the desert iguana and give rise to the hope that similar procedures may be successful adjunctive therapies in certain human toxic diseases.

NATIONAL CONFERENCE ON RURAL HEALTH

Third Annual Meeting, held in the Palmer House,
February 6 and 7, 1948

Dr. F. S. Crockett, Lafayette, Ind., Presiding
Friday, February 6

The conference on Rural Health of the American Medical Association was called to order at 9:45 a. m. by the Chairman, Dr. F. S. Crockett, Committee on Rural Medical Service, American Medical Association.

Chairman Crockett: Our two previous annual conferences dealt with the need for better health facilities and health services in rural areas and sought to evolve technics that would secure this improvement in rural living. The common interest of doctors and farmers resulted in expanding our American Medical Association Committee on Rural Medical Service to include advisory members from the four larger farm organizations. This addition of advisory members from the farm groups has made possible a bilateral approach to all our common health problems free from any dominant unilateral self interest.

The program that we are giving today and tomorrow is the result of full and free conference which was held last October with our advisory members. Any one present is privileged to voice his opinion, no matter how controversial. If there are things which seem to you important and of which the profession apparently is not aware, they should be brought out in these conferences.

The program this year takes up the health status of the rural child. Good health cannot be imposed on any individual or community by some higher authority; it can be achieved if those concerned want it more than anything else. Our people must be shown that children should be kept free from many of the diseases of childhood with their resultant disability and mortality. By providing adequate education in health matters, it is not the intent to make doctors of all the people, but if persons can be educated in health matters to the point where they will seek health while still curable and take under guidance the necessary measures to prevent the spread of disease, then will we have the fulfilment of many of our objectives. We look to this conference conducted in cooperation with the National Cooperative Milk Producers Federation, the Farmers Educational Cooperative Union, the National Grange and the American Farm Bureau Federation to mark another milestone in our progress toward better rural health.

Address of Welcome

Dr. George F. Lull, Secretary and General Manager, American Medical Association, Chicago: We feel that the problems about to be discussed are of vital interest to doctors as well as to members of these important agricultural groups. We have, following this meeting, a Congress on Medical Education. Some of the work being done by the medical schools fits in with the work recommended by many of your groups, that is, in certain states scholarships are being set up for men who after the completion of the study of medicine will go to rural areas and practice where there is a need for a general practitioner. The distribution of these doctors to rural areas is not a simple matter. However, this step by the institutions of learning is in the right direction and may help solve this problem.

It is also of a great deal of importance to us to bring into this conference the health of rural children. To improve the health of this group, the physicians must have the aid of farm families. The Hill-Burton Bill is a step in the right direction for improved health. It means that more hospitals will be available for persons in rural areas. These hospitals will go, hand in hand with better medical care, because the better physicians will be attracted to areas where adequate hospitalization is available. A great deal of benefit is going to result to the rural areas, but it isn't going to be accomplished overnight. It is important that these hospitals be properly located. The site should be selected with care and should depend on need rather than on political expediency. Most places have gone into this with a great deal of care and the results of the surveys show that the communities and the agencies involved are vitally interested. We hope that you enjoy your stay with us and that we can all go away feeling that we have accomplished something.

Health Problems of the Rural Child

Dr. Lee Forrest Hill, Past President, American Academy of Pediatrics, Des Moines, Iowa: In my assignment to point out the health handicaps imposed on rural children by the maldistribution of medical services and facilities between rural and urban areas, I am confronted by the difficulty that no standard has been set up defining the kind and amount of medical care that a child should receive, whether the child lives in the city or in the country. Were such a standard available, it would be simple to list categorically the deficiencies of the health services available to the rural child. It seems reasonable in the absence of an established standard to use the urban child under pediatric care for comparison with the rural child in order to bring out the health problems of the latter.

The pediatricians of the nation are located almost exclusively in the larger cities. Less than one fourth of the child population receives its medical care from pediatricians. Over three fourths of the children in the United States are dependent on general practitioners for supervision of their health. General practitioners, receive, even in recent years, only about two months of training in pediatrics during their single year of internship. I agree with those who feel that the general practitioners are doing an excellent job and that what is needed is more of them and more of them in rural communities. But if the health problems of the rural child are to be met adequately it is essential that the general practitioner of the future receive more pediatric training than has been provided for him in his medical school education and in his internship in the past. The current movement toward two year internships for the general practitioner, four to six months of which would be spent in pediatrics, would appear to be a long step in the right direction.

Among the health problems of the rural child, first is the relative unavailability of the preventive services. Nearly one half of the average pediatrician's practice is devoted to health supervision of well infants and children. Customarily, infants are brought to his office monthly for examinations during the first year, every three months during the second year, every six months from the second to the fifth year and at yearly intervals throughout the remainder of the growing period. The purpose of such regular examinations is to appraise the adequacy of growth and development as shown by physical measurements and by mental and motor achievement. Thus disease may be detected in its incipiency and corrective measures instituted before irreparable organic damage has resulted.

A careful physical examination is performed at each visit, including acuity of vision and hearing tests at or near the beginning of the school years. Simple laboratory tests of the urine and blood are done, and tuberculin tests are made at intervals of three years. Immunization procedures are carried out at the proper age in infancy, and appropriate booster injections are given in later childhood. The adequacy of the diet, including vitamin and mineral supplements to meet nutritional needs as these vary with the growth periods, is reviewed at each visit. A final and most important phase of the health examination is the parent-physician conference in which parents are instructed in what to expect in the way of behavior at the various age periods and advised as to how each major situation should be met. The prevention of emotional maladjustment in the home, at school and among playmates is an important function of the regular health examination.

Obviously this sort of medical care is difficult for the rural child to obtain. The busy rural general practitioner just has not had the time, even if he has had the training, to provide the rural child wi[illegible] important phases included in the periodic health ex[illegible] In t[illegible] cities [illegible] well [illegible]hild conferences are available to the children of less well-to-do families. In many states health departments sponsor child health conferences in rural areas, but the bulk of rural children are still without the advantage of this type of health supervision. This is equally true of the school health examination. Until general practitioners are available to provide preventive health services for rural children, steps should be taken to increase the number of well child conferences and to establish more widely the school health examinations.

A second major health problem faced by the rural child is the relative unavailability of the specialist's consultation services. From the more remote areas the job of getting an ailing child to a specialist in a medical center is not easy, the result being that the visit may be delayed or not even attempted. Methods have been suggested, some of which are already in operation, for bringing to the rural areas more adequate consultation service.

A third health problem in which the rural child is handicapped compared to his urban contemporary is the matter of the facilities for the treatment of the more serious illnesses. Scientific medicine has made great advances in recent years. Today more than ever before the laboratory is essential in the diagnosis of disease and in the management of treatment. But for rural children no such nearby facilities are available.

The Hill-Burton Hospital Construction Act is aimed at remedying this situation. But the rural general practitioner must be supplied with more than hospital beds if his child patients are to have the full benefit of what modern medicine has to offer. He must be given all the necessary adjuncts with which to do his work. Pediatric hospitals can be of great help by rotating members of their resident staff through these remote hospitals. Thus, plus weekly or semimonthly visits to the outlying hospitals by a senior member of the staff for the purpose of making rounds or holding a clinic for the neighboring general practitioners, would do much to provide the rural child with the advantages enjoyed by the urban child.

A fourth health problem, the premature infant, offers a particular hazard in rural areas. One half of the deaths in the neonatal period occur among prematurely born infants. Many of these lives could be saved. But, special facilities and personnel specially trained in the care of the premature must be provided. The American Academy of Pediatrics, through its Committee on Fetus and Newborn, is engaged in a project looking to the establishment of premature stations at strategically located centers in every state in the country. It is contemplated that ambulances equipped with incubators and oxygen will be made available to transport the premature infant from the place of birth to the premature station.

There are many other health problems which residence in a rural community creates for the child, but perhaps these I have mentioned are sufficiently illustrative to point up the need for instituting measures which will lessen the gap in medical advantages between the rural and urban child. The health problems of the rural child can be met in part at least by the attainment of some or all of the following objectives:

1. An increase in the number of physicians in rural communities.
2. Increased emphasis on pediatric teaching in undergraduate medical education.
3. Lengthening of internship for the general practitioner going into rural practice to two years, six months of which should be devoted to pediatrics especially adapted to the problems of the rural child.
4. Construction of rural hospitals and health centers as proposed under the Hill-Burton Bill with provision being made for adequate laboratory and other technical personnel.
5. Rotation of pediatric residents from approved hospitals in pediatric centers through these rural hospitals for the benefit of both the residents and local doctors.
6. Frequent visits by consultants from the staff of the pediatric hospitals to the rural hospitals for ward rounds and teaching clinics.
7. Increased provision for postgraduate education in pediatrics of rural general practitioners both at the pediatric center and in the local communiteis.
8. Development of more adequate school health services by physicians trained for this purpose.
9. Coverage of all counties by public health services, including the public health nurse.
10. Establishment of premature stations wherever needed in each state.

I have read the booklet prepared by the Committee on Rural Medical Service of the American Medical Association. It is gratifying to learn of the seriousness of purpose with which the problem of extending better medical care into rural communities is being attacked. The reports of the chairmen of state medical committees and those of representatives of the medical schools clearly indicate that remarkable progress is being made. The American Academy of Pediatrics will be happy to contribute its services in every way possible toward improving the health of rural children.

Mrs. Charles W. Sewell, Administrative Director, the Associated Women of the American Farm Bureau Federation, Chicago: According to a statement made last September, 53 per cent of the children who were then entering the nation's schools were from rural homes. David S. Jordan remarked that the education of a child, and I would like to add, his health, begins a hundred years before his birth. With fewer hospitals and clinics to provide prenatal care available, the rural child often has handicaps dating from birth that penalize him for an entire lifetime. About seven eighths of the children born in cities, but less than half of the rural children, see the daylight first in hospitals. Authorities tell us that more than 40 per cent of all farms are still without electric power. Hence, in many sections children lack proper light for studying. Too many farm homes are still without running water, sewage disposal and other sanitary safeguards. I believe that the day is not too far distant when we will require the nutrient content of the soil on which our food is grown to be declared to allow us to know we are buying food and not filler. We used to say "children are safer in the country," yet the National Safety Council tells us that farm accidents are among the highest that they have recorded.

The migrant child of rural America is another new development. Health needs are not closely supervised, and many disastrous epidemics are directly traceable to these children who come and go as the seasons change and the families move on to work in other harvests. I believe we can make the needed changes to keep the rural child happy and healthy if we work together—the medical profession, the farm people, the public health officials and the citizenry. The fine program in health carried on by our national 4H clubs demonstrates what can be done. My own organization has this year raised $12,500 to be used in the establishment of scholarships or fellowships in research on poliomyelitis. We need better distribution of doctors, dentists, nurses and hospitals. We need better public health facilities and more programs in school health.

Many state organizations have taken the lead in securing legislation that will protect the health of the rural child. Many have promoted the prenatal plans for better care. We need your help to establish hot school lunches for all our children. Agriculture should not be expected to carry the load alone. As a representative of the American Farm Bureau Federation, I wish to express our appreciation to this committee for helping the American Medical Association and perhaps all of America to rediscover rural America and its children.

Study of Child Health Services

Dr. Crockett: We next have on the program three papers on the study of child health services.

Dr. John Hubbard, Director of Child Health Studies, American Academy of Pediatrics, Washington, D. C.: (Read his paper, which will be published in full in The Journal.)

Dr. Katherine Bain, Director, Division of Research in Child Development, U. S. Children's Bureau, Washington, D. C.: Economists have pointed out that children in the city have and children in the country have not, but the separation of urban from the rural population is not nearly as clearcut as this in regard to medical care. People do and should cross county lines or even state lines in seeking adequate health services. How much migration actually takes place for treatment and diagnostic service we do not know, but the big urban center certainly supplies not only the population of that county but the surrounding area. Persons in a so-called rural county adjacent to a metropolitan county have more chance of getting adequate medical care than those in an outlying county. This county grouping which Dr. Hubbard has described was devised to take into account the factor of accessibility of care, but with this factor of accessibility weighed, you have seen the extreme maldistribution of personnel and hospitals that exists. Now what does this maldistribution mean in terms of actual care received by children?

Previous studies such as the National Survey of 1935 used the device of a personal interview with a sample of the population. The academy's study went at the problem from the other end. The study gathered data from the persons rendering service, from the physician, hospital, clinic and so on. The study has collected these types of data for each county in the United States, all the visits made by the physician to the child's home or the office visits of children on an average day, all the children in hospitals in an average day, all the children visiting clinics on an average day—these taken together are an index which we have called the total volume of medical care. This is fairly complete coverage, and because coverage is complete, we are justified in making certain rates against the child population. We find that a thousand children in Illinois or in Maryland and the District of Columbia have, on an average day, twice as much medical care as a thousand children in Alabama. Are the children of Alabama less in need of medical care? I would doubt it. One is forced to accept the fact that the children of Alabama get not more than one half as much care as they actually need.

With regard now to total volume of medical care using the county group classification, on the basis of eight states selected because they are fairly representative of the United States as a whole, we find in the metropolitan and adjacent counties the rate of total volume of medical child care on one day is 17 of 1,000 and the rate for the isolated counties is 12.5. Again it is shown that the children in or near cities have more medical care than the children in the outlying district.

In addition to more in quantity there is also more in quality. The metropolitan and adjacent counties have more hospital, clinic and specialist care. Children in and near cities have twice as much hospital care, five times as much clinic care and four times as many visits to the pediatrician.

Dr. Hubbard has shown the maldistribution of doctors and hospitals. I have shown what maldistribution is in terms of the amount of medical care. What does this mean in terms of health for children? What is the end result? I don't believe that we know the whole answer. One item of information: Infant mortality for the five years of 1941 to 1945 was 38 for the metropolitan area and 47 for the isolated county. The infant mortality rate has long been considered a delicate index of the health of the community. I think it is fair to assume that one important cause of the more favorable infant mortality of the metropolitan and adjacent counties was the quantity and quality of available medical care.

Dr. Henry G. Poncher (Chairman, Illinois Child Health Studies, American Academy of Pediatrics): The need for improvement in the medical care health supervision for children has been established by the survey. There is a dramatic contrast between the adequacy of all health aspects and facilities for children in urban and isolated rural areas. This includes all the services, physicians, dentists, hospital facilities and community health services. It is agreed that the mental health of adults depends on the care they received as children. Health depends more on well trained doctors than on improved medical facilities and more on greater availability of community health service than on hospital facilities when children are sick. While improved physical facilities are important, the judgment and the skill of the individual physician in matters pertaining to child health is paramount. Such skill is the result of training and experience. It has been shown that the general practitioner provides 75 per cent of the medical care for children, yet nearly one half of the physicians in the survey report that they have had no hospital training in pediatrics. I think the general practitioner has done an excellent job, considering the task with which he is faced. The point I would like to make is that to provide one of the important improvements in medical care for rural children we have to give some definite consideration to medical education. As a result, the American Academy of Pediatrics has seen fit to appoint a Committee on Child Health Improvement representing various parts of the country. The further step then taken is to appoint a Committee on Pediatric Education. It is becoming increasingly apparent that the planning of undergraduate and graduate courses must provide for the general practitioner in the field of pediatrics in order to fulfil the health needs of the community.

I would like to point out just how the survey was started in Illinois and the mechanization by which some help can be obtained for the definite situation. This study was channeled through the Illinois State Medical Society because there is an organization within the state composed of ten councilor districts. The whole study was based on the fact that when the results were obtained they would be returned to the local areas for planning in public health, so that while we not only have details with regard to child care, we have an organization to follow-up with that data.

In the southern part of the state there is a definite area almost exclusively isolated. There is no consultation service and no licensed pediatrician in that area, and as a result the Illinois State Medical Society has voted to establish a diagnostic center in that area. That is one of the palpable means by which rural help can be obtained.

A pamphlet put out by the Illinois State Medical Society is entitled "Doctors and Horses." It is an excellent, concise description of how improvements may be brought about.

Education is an exceedingly important factor in this problem. The College of Medicine of the University of Illinois has seen fit to admit 50 per cent of its students from urban areas; 50 per cent of the places are saved for those outside of Cook County. Furthermore, the Illinois State Medical Society has gotten together with the Illinois Agricultural Association and raised $100,000 to send young men from rural areas to medical schools with the idea that those men are more likely to go back to rural areas. Another thing that has been done by the Department of Pediatrics is to provide that our men must spend at least six months of their pediatric training in a semirural area.

I would like to stress two points: first, we must improve our pediatric education and make pediatric education available to more persons who will go back to rural areas; second, the communities themselves must take the initiative in asking for improved medical facilities.

Rural Youth and World War II

Dr. Maurice H. Friedman: The people of this country have been frightened by a lot of irresponsible estimates regarding the draft figures, some of them emanating from an agency of our federal government. It is unfortunate that such frank misstatements of fact have been broadcast. It has been claimed time and time again that the percentage of rejectees from rural areas was higher than that of rejectees from our cities and metropolitan areas. I should like to emphasize the fact that the draft rejectee figures have little to do with measuring the health of any community.

I have had frequent conferences with members of the selective service administration in Washington and I should like to project for you the actual figures which they gave me and which they checked item by item with every decimal point before I came out here to talk with you.

For the United States as a whole, the number of men (white only), was definitely higher than from the cities. From the country 57.3 per hundred were accepted, and from the city, 54.7. For every section of the country, the number of men accepted from the rural communities was higher than that from the cities. The acceptance rates were lower for the purely farm population as opposed to other populations than for the remainder of the rural population. Nevertheless, the acceptance rates for farm only are higher for the United States as a whole for white men than they are for the cities. Statements that the rejection rates in rural areas were higher, reflecting poor health conditions, will have to be branded as false, if we can accept the original data of the Selective Service System. That condition does not pertain to the same extent to the Negro. The figures for the Negro show definitely lower acceptance rates for Negro registrants in all categories. Note that the farm acceptance rate is slightly lower than the urban. The Negro farm rates are even lower than the Negro rural rate as a whole. In some sections of the country, strangely enough in the South, the rural acceptance rate for Negroes was above 59, higher than the urbanite rate, which is 56.5. The Negro rejections were largely determined by venereal disease, educational deficiencies and mental disease. Those three factors alone accounted for 60 per cent of all Negro rejections.

I made an adequate statistical allowance for errors. There were twenty-four categories of defects which could be compared in each of these states, which makes seventy-two possible comparisons. Of these seventy-two categories, in twenty-nine there was no difference whatsoever between the rural and urban populations; in twenty-three categories the rural population had definitely fewer defects than the cities, and in twenty categories the city rates were definitely lower than the country: Altogether there was no difference between the urban and rural defect rates. For most of these categories, the differences were not consistent. There were three classes of deficiencies which were consistently different in the rural and urban population. The category of eyes, ears and abdominal organs. Those three categories were lower for the rural population in all three states than for the city population. In those three categories (eyes, ears and abdominal organs) the farm and rural population as a whole had lower defect rates than the city. The differences between these defect rates were so great as to exclude any sampling error. On the other hand, there were three categories in which the rural rates were higher. Mouth and gums, throat, and educational deficiency were the categories for which the rate was higher in the rural areas of all three states.

With the cooperation of the officers of the selective service, I obtained permission to see the raw data county by county for the entire United States. I did not have sufficient time or energy to prepare the data for the entire country, but I took three representative states in this part of the country, Indiana, Iowa and Illinois. Every county had its own draft board. My problem was to select purely rural counties from purely or overwhelming urban counties. I got the census figures and I segregated those counties in which there was not a single community over 2,500 in population from those in which the populations were almost entirely urban excepting Cook County, Chicago. By counting up every defect listed in these counties in these three states, I prepared a tabulation of defect rates for these three representative states for the urban and rural populations. I took twenty-one rural counties in Illinois with the aggregate population of 422,000 and contrasted the total defect rates with those of the city of Chicago and four other urban counties. I was able to get the figures for seventeen purely rural counties in Indiana with an approximate population of 211,000 persons and contrast total defect rates with the defect rate as found in Lake County, which is almost entirely urban, and three other urban counties in Indiana. I was able to segregate thirty purely rural counties of Iowa with an aggregate population of 452,000 and contrast the figures in these counties with those for Polk County and the six other urban counties.

Tabulation of the total number of defects or the defects in one particular category is in itself no measure of the health of that community. The selective service system was not asked to evaluate the health of this country. They were asked to get combat soldiers and sailors for our armed forces, and they did that job and did it magnificently. They were not concerned with the number of other indexes of public health. What do those defects mean? Of all the defects listed by selective service, over half are structural abnormalities and have no relation to disease whatsoever. The selective service system has always been careful to point out this fact. They have said time and again that the emphasis on these defect rates has been much too great and has engendered many conclusions that are unjustifiable in regard to national health. They have said, for example, something like this; the fact that the terminal phalanx of the middle finger was missing or that a man was less than 60 inches in height were cause for rejection but in no way reflected on the health of that individual. Of these structural abnormalities, many are minor, congenital defects; a number of others are the result of injury which has been repaired, and a great many of these defects are not the result of lack of medical care but the direct result of medical care. When a limb is crushed by farm machinery and a surgeon amputates that limb, you have got another defect in the selective service system. A large segment of draft defect figures show perforated eardrums which are the result of medical care and not the lack of it.

Here is something more astonishing. Some of these defects are a measure of our good health and not the reverse. The fact that a diabetic lives long enough to be examined by a draft board is only due to the continued good medical care available in this country. Children with rheumatic heart disease carrying themselves into adult life by skilful medical care form another significant group with defects listed by the selective service system.

I should like to ask one uestion: is a corpse healthier than a rejectee with diabetes?

DISCUSSION

Dr. Muenzer, Toledo, Ohio: I would like to ask Dr. Friedman why they still list hypertrophied tonsils as disease. Having examined men of two world wars, and having watched a group of athletes for twenty-five years, I have failed to find that the size of the tonsils had influence on the men. I don't think any one should hold hypertrophied tonsils as a diseased condition, as we understand the term disease.

Dr. Mundy: The proponents of socialized medicine were guilty of a great deal of ignorance or we could question their intelligent use of facts and figures which they have quoted from the draft examinations when they tried to use these figures in an attempt to put socialized medicine over in this country. They ought to have enough humility to admit that they were ignorant of those things or that they tried to slip something over.

Dr. Friedman: In the selective service statistics there are several broad categories of defects, one being "throat." A large number of reported defects were hypertrophied tonsils, and I agree that it is not necessarily a disease. Various draft board examiners will record tonsils as being large or small, depending on how they feel about it. That is not an objective measurement. There are also exceedingly different policies in each area. Every defect listed was higher in Iowa than in Indiana or Illinois. One cannot compare the rural population of Iowa or the city population of Illinois, not because they are fundamentally different but because they are in a different army area. I was startled on examination of the differences in policy from one area to another. The number of large tonsils is attendant not on the tonsils but on the draft policy in that area. In the rural areas of Iowa there are more physicians than in the rural areas of Indiana and Illinois, yet the number of defects recorded was higher in Iowa, both city and country, than in Indiana or Illinois.

Dr. Boies (Minnesota): If nobody wants to ask questions, it would be nice to extend the courtesy of the floor to Dr. Friedman until the time expires.

Dr. Friedman: I think it would be very wholesome if the responsible agencies in each community would get together and try to educate themselves as to how to gage the health of their community. It is not merely a question of doctors or hospitals. There are a number of other factors regarding health. Dr. Roscoe Hyde and his co-worker in Boston used the selective service statistics from that district to isolate those factors which were responsible for defects. He went back and graded communities from which these men came. The community is graded as to quality on the basis not of medical care but of per capita wealth, educational facilities, welfare activity, public works and all environmental factors which go to make a good community. Other factors that he took into consideration were housing conditions and density of population. Average income in a separate factor. We found, for example, as has been found time and time before, that tuberculosis depended more on the density of the population than on the economic status or any other separate index and that certain kinds of mental diseases were related to some factors and other kinds of mental disease to other factors. For example, mental deficiency did not occur in the Irish or the Jews. Some persons might wish that the members of the medical profession could convert everybody into Irishmen or Jews. Chronic alcoholism did not occur in the Chinese; it was related more to population density than to anything else. Psychoneurosis is related to other factors. It is important to remember that one cannot discount the importance of church, life, family life and other wholesome environmental factors in regard to mental disease defects listed under the nervous system. For ten years the Council on Churches of Christ in America has sponsored symposiums between physicians and clergymen to foster cooperation on this very problem. The communities as a whole would do well to recognize that.

I cite a few figures to prove that the number of doctors, although important, is not the controlling factor. During the war, when over 30 per cent of our active, young physicians were in the armed services, the civilian population had available to them less than two thirds of their ordinary supply of doctors. Over one third were in the army and navy. Despite this great decrease in available medical services, the maternal mortality in the United States dropped from 3.8 per thousand of live births to 2.1 per thousand live births in 1945. Now some would say that if we can do so well with a third less physicians, let's get rid of all of them! That is the kind of logic that has been used by many persons who have discussed these questions. Infant mortality dropped from 47 per thousand live births in 1940 to 38.3 in 1945, again associated with or contemporary with a decrease of over 30 per cent in volume of medical service available to the civilian population of this country. Caution must be exercised. Merely because two things happened at the same time does not necessarily men that they are closely related. These various facts demonstrate that other factors than the number of doctors are important in health and that in order to estimate the importance of the services of physicians and hospitals one must make proper allowances for all the other factors which are of equal and sometimes greater importance.

Dr. Margaret W. Gerard, Institute for Psychoanalysis; Consultant for the Illinois Children's Home and Aid Society, Chicago: There is more and more talk about so-called psychosomatic medicine. All illness has to do with the lack of adequate behavior of the body, the lack of real integration of the body, which includes the nervous system and all the other organs concerned in health. Many of the diseases have psychologic elements. I would like to discuss some of the factors in the development of a healthy, well integrated individual. The pediatrician has taken over very adequately in many instances the understanding of child psychology. It is the pediatrician, and in some instances the family doctor, who is expected to give information as to how the child is to be brought up. It is in the first few years that the child is mostly influenced. Whether or not he will develop a mental disease, a neurosis or a neurotic reaction which has its somatic element, will be determined in these earl years. Great modifications will vary the ramifications of that disease, but those early years are extremely important.

In most hospitals today, children are cared for affectionately. They take food better. They develop better. We have certainly much less marasmus, perhaps as a result of that affection. We used to see marasmus many, many times in the old days. I have mothers ask, "Am I not going to spoil the baby if I let him do what he wants to do and feed when he wants to feed?" When one goes to the extreme, the later training period is much more difficult, but the child's serenity relative to comfort in living within the first year of life, if he is fed enough, if her is fondled and if he does not have periods of hunger as well as other kinds of pain, makes his psychologic attitude toward living such that he will accept training and accept the demands which life makes on him to grow up

The child with behavior problems always wants to be sick, vomits easily, is very often a child whose incentive to do the right thing is not sufficient because he hasn't had enough reason to think that doing the right thing in the living world is worth the trouble. The old methods of training instituted bowel control within the first month or so and urine control within five or six months if possible. We know now that the child is not physiologically capable of control of bowel movements at that particular age. Physiologic adequacy in relation to the rectal functions and renal functions do not come into operation until the fifth or sixth month and the urinal capacity occurs around the latter part of the first year. A child trained earlier develops difficulties relative to his feeling of capacity, and therefore the child is apt to change his whole attitude toward adaptation. Children develop the feeling of inferiority as the result of this early training. Such children give up learning adequately. They don't achieve as well as they should because they have learned early that they can't do the things they are expected to do. We find children rather despairing about this capacity, and therefore some of the illnesses which come on without any apparent reason and which are fairly resistant to the doctor's treatment have some of their background in the relationship of the child to the parent. Such training should always be tuned to the child's developmental capacity. When he is expected to do something beyond his capacity, he is going to get into difficulties. Not only does this training have to be carried on relative to the capacity of the individual to develop good, healthy habits and social relationships and good physical stamina, but it has to be fairly consistent. We get an inconsistency in our city parents, by whom training is carried out for a day or two; then the parent is busy and doesn't bother. For the next two or three days the child doesn't know what is expected of him. He learns that under some circumstances he doesn't have to do what is expected of him under other circumstances and he never develops adequate habits. He hopes to manipulate his life so that the circumstances which he can protest are present.

Some persons have psychiatric hypertension which is partly relative to their more aggressive reactions. They are persons who have aggressiveness just under the surface. When one follows back into their history one finds a situation in which there was an inconsistency in their training as one element in the difficulty; inconsistencies which made their habits rather fragile, habits which were carried through only under certain circumstances. If the person is not quite sure whether he is going to blow up, his parents have not been consistent in their demands on him. He is under the tension of keeping himself under control, and the result of this tremendous tension is a secondary somatic reaction or secondary sympathetic reaction which involves the blood vessels—a vascular reaction to a psychologic condition. We all are aware of these simple physiologic things. We see them all the time.

The important factor is proper training at the proper time and consistently. A child needs a certain amount of punishment to make him realize that there are certain things he must really do or life will be too difficult. A child can't grow up by love alone. Children develop much better with a certain incentive than they do without any incentive. The main incentive among children is praise.

Another important point is the role that sex education plays in the development of the child. Youngsters get in difficulty because of misinformation which they receive from companions because parents are not willing to talk to them and misinformation which they got from visual scenes which they misinterpreted wrongly. Therefore we find that the child, to be physically and mentally healthy, must have answers to questions about how the body functions relative to any kind of physiologic activity as well as reproduction. He is capable of understanding it without any harm if his questions are answered scientifically. He will get into difficulty without information, because his curiosity leads him astray. Al lkinds of abnormalities develop in youngsters as a result of misinformation. There are books now which are very helpful in letting parents understand how easy it is to answer a child's questions scientifically.

I would like to discuss the factors relative to physical conditions at adolescence, but I haven't time enough. That is the point at which we see many psychosomatic reactions. It is the period when the early bringing up begins to show its bad effects and when the children begin to develop not only mental disease or neurotic diseases, but somatic diseases of psychogenic origin

(To be Continued)

JOINT COMMITTEE FOR THE COORDINATION OF MEDICAL ACTIVITIES

Report of Meeting in Chicago, Dec. 6, 1947

(CONDENSED FROM THE OFFICIAL MINUTES)

The Joint Committee for the Coordination of Medical Activities met Saturday, Dec. 6, 1947, in the Board Room of the American Medical Association Building in Chicago. The Chairman, Dr. Ernest E. Irons, called the meeting to order at 9:45 a. m. Members and liaison members present were:

Dr. Irvin Abell
Dr. Donald G. Anderson
Brig. Gen. George E. Armstrong
Dr. Walter L. Bierring
Dr. G. O. Brown
Mrs. Kity Ives Coleman
Mr. Ralph G. Creer
Mr. Graham L. Davis
Dr. W. Palmer Dearing
Capt. William E. Eaton
Dr. Lester J. Evans
Rev. John P. Flanagan
Dr. J. F. Hammond
Dr. Fred V. Hein
Dr. Elmer L. Henderson
Mr. J. W. Holloway Jr.
Dr Hugo V. Hullerman
Dr. Ernest E. Irons
Dr. George F. Lull
Capt. Frederic L. McDaniel
Dr. J. J .Moore
Dr. H. B. Mulholland
Dr. Walter L. Palmer
Dr. James E. Paullin
Dr. Carl M. Peterson
Dr. Richard J. Plunkett
Col. Paul I. Robinson
Capt. Robert V. Schultz
Dr. R. L. Sensenich
Dr. E. R. Serles
Dr. H. H. Shulders
Mrs .M. Virginia Shuler

NAVY TRAINING PROGRAM FOR MEDICAL AIDES IN THE PACIFIC ISLANDS

Dr. James E. Paullin moved that the Joint Committee heartily endorse and recommend the training program in the Pacific islands, as outlined by the Bureau of Medicine and Surgery, and that a subcommittee consisting of Dr. Edward L. Bortz, President of the American Medical Association, Dr. Lull and Captain Schultz be appointed to suggest a name for the school and its graduates.

CONFERENCE ON COOPERATON OF THE PHYSICIAN IN THE SCHOOL HEALTH AND PHYSICAL EDUCATION PROGRAM

Dr. Fred V. Hein, a member of the staff of the American Medical Association's Bureau of Health Education, presented the following statement:

> It was felt that the American Medical Association was rightfully concerned with school health problems and programs, first becouse there are an estimated 20,000 physicians in the United States who are serving the public schools directly as either full time or part time school physicians. In addition, many thousands of physicians are concerned with school health as it relates to the care of the students and their families. With these facts in mind a Conference on Cooperation of the Physician in the School Health and Physical Education Program was arranged to be participated in by physicians and educators and was held in Highland Park, Ill., Oct. 16-18, 1947. Invitations to attend were sent to state medical societies, state departments of health, state education associations and some national voluntary health agencies. One hundred and twenty persons representing ninety agencies or organizations in thirty states and one territory attended the Conference, and twenty-six consultants drawn from the fields of public health, public education and medical education participated actively. The main purposes of the conference were to implement the health service divisions of the public schools, to provide for an interchange of information among the various personnel and to define the role of the physician in relation to health aspects of physical education and athletic programs. School health policies have been rather well established, and authoritative documents that set forth those policies are available; however, there is a great gap between the practices in the schools and the established policies.
>
> Principal recommendations emanating from the conference which might be of interest to this Joint Committee are: 1. Wherever there is a school, the local community should budget for a school health program and in that budget there should be adequate provision for the salary of a well qualified medical adviser on either a full time or part time basis. 2. The physician's time in the school can be best utilized if he is employed as a medical adviser rather than as a mere medical inspector. 3. Routine medical examinations should be spaced at three year intervals during the school life of the child. 4. The schools should definitely discourage the practice of postponing inoculation to the period of school entrance, because immunization is necessary for protection particularly in infancy and in the preschool period. 5. Cumulative health records should be a part of the child's total school record throughout his school life. 6. Physicians and physical education teachers should arrange joint meetings for discussion of mutual problems.
>
> In general, I think it can be said that the educators were most receptive to the American Medical Association's sponsorship of this program. The reactions have been most excellent. A brochure containing the full recommendations of the conference and the section reports it being published and will be available for wide dissemination to schools, health repartments and medical groups throughout the country.

THE GENERAL PRACTITIONER

Dr. Bierring submitted the following report for the Subcommittee on a Specialty Board for General Practitioners:

> Since the last meeting of this Joint Committee, a number of developments have taken place. One was a request from the secretary of the American Academy of General Practice to a number of the members of the Joint Committee and to various prominent physicians to become members of a Coordinating Committee for General Practice, the composition of which would be similar to that of this Joint Committee. The list of those invited included Gen. Paul R. Hawley, Dr. George F. Lull, Dr. B. R. Kirklin, Dr. William S. McEllroy, and Dr. James B. Waring. Some accepted the invitation; others did not. It appears to be an interesting gesture. The membership of the academy, which was organized barely six months ago, seems to have grown prodigiously, and already an executive director has been employed as a reputedly extremely high salary.
>
> Other organizations in the field of general practice are being promoted, but it does not seem that the specialty board in Indiana—the Indiana Board of General Practice—is progressing very rapidly. I am not certain that there is a need for all these outside organizations. Traditionally and historically, the American Medical Association has been the organization for general practitioners and has within itself the machinery, and the inclination to bring about a definite elevation of the status of the general practitioner.

Dr. Sensenich informed the committee that the president of the American Academy of General Practice had recently stated that the formation of the academy is a response to an insistent demand o nthe part of general practitioners that there be a specific organization that will look after their own particular interests. Dr. Sensenich also said: In conversation with the president of the academy, I called to his attention the fact that practically every organized specialty group had early in their existence taken the position that they were not policy-making bodies; I told him that I hoped the new academy would not have some other conception, and he said there had been no thought of such a position.

Dr. Abell remarked that he had heard that the general practice section of the Los Angeles County Medical Association has established a subsection on surgery! Dr. Paullin asked in what part of the country the movement is most active, and Dr. Lull replied that it is rather general throughout the country.

Dr. Henderson spoke as follows: This movement is pretty general throughout the country. On the surface, at least, it does seem to be a movement in conflict with the American Medical Association. The American Medical Association is the general practitioner's organization; anything that any other organization can do for the general practitioner, the American Medical Association can do and is doing. It seems to me that it would be a mistake for any official of the American Medical Association to become a member of any other type of general practitioner's group as organized today.

According to Dr. Moore, the academy says that it is not in opposition to the American Medical Association because one of its membership requirements is membership in the American Medical Association. Dr. Palmer suggested that perhaps one of the motivations for the organization was an attempt to bring pressure on the hospitals to resist the efforts of the American Medical Association to elevate hospital standards. Dr. Bierring thought that there might be some ground for complaint but said that in his opinion the American Medical Association is doing all it can for the general practitioner. He remarked that one of the first objectives of the academy is to promote and maintain the "general practice of surgery," and he wondered what constitutes the general practice of surgery!

Dr. Anderson stated: The Council on Medical Education and Hospitals is doing nothing that would in any way exclude the general practitioner from the hospitals. In certain institutions the lay boards have interpreted the Council's "Essentials" to mean that only diplomates of the specialty boards should be on the staff; they have been in error, and the Council has so informed the institutions.

TAFT-SMITH-BALL BILL VERSUS WAGNER-MURRAY-DINGELL BILL

Mr. J. W. Holloway Jr., director of the American Medical Association's Bureau of Legal Medicine and Legislation, presented a statement contrasting the Taft-Smith-Ball bill and the Wagner-Murray-Dingell bill.

COMMUNICATION FROM MISS MARY SWITZER

The Chairman asked Dr. Shoulders to read a letter which Miss Mary Switzer, assistant to the Federal Security Administrator, had sent him in reply to his request that she discuss at this meeting matters of current interest, particularly the Bipartisan Committee on Reorganization of Federal Agencies, which Hon. Herbert Hoover is chairman. The letter reads:

As you know, the American Medical Association is one of the sponsoring organization of the National Conference on Family Life to be held in Washington, D. C., at the White House, May 6-7-8, 1948. At a recent meeting of the Board of Trustees, Drs. Wingate M. Johnson and James R. Miller were named the official representatives of the American Medical Association. In addition to these official representatives, I hope that other members will be asked to serve on various committees working up material *for presentation at the conference. Our group may be interested in just* how comprehensive the program o fthe conference will be. The subject matter *has been divided roughly into three large headings: (1) background* —which will be a description of the modern American family, where it lives, what its background is, income distribution, legal status, and the like; (2) the family as part of the social group—which will be concerned with what the psychologists call "the dynamics of family interaction," how they form, mature and function, probably an anthropologic approach in simple terms: this section will deal with the inter-personal relations *in family living and so on, and (3) action areas of family life, of which* health is one. Others include home management, housing, education and social welfare.

In addition, the following five points will be woven into the outline: (1) the role of spiritual values in the development of stable family life; (2) the meaning of democratic family life; (3) trends in ascandant-submissive roles of husband and wife, factors relating to success and failure in marriage: (*a*) economic living and social factors, and (*b*) women's conflicting values; (4) dominant patterns of authority and discipline in the family, and (5) cultural pressures on individual members of the family.

The Chairman regretted that Miss Switzer had omitted a reply with respect to the Reorganization Committee, and Dr. Dearing said that little is known about it as yet, except that a bill has been introduced in Congress to provide additional funds for the committee's work. The Chairman announced that the subject would be placed on the agenda for the next meeting.

HOSPITAL SURVEY AND CONSTRUCTION PROGRAM

Dr. Dearing presented the following information with respect to the Hospital Survey and Construction Program:

The Hospital Survey and Construction Program was a subject of much discussoin at the recent conference of the state and territorial health officers; The response of that group is indeed gratifying and encouraging.

Thirty state plans have been submitted and twenty-three have been approved *by the Surgeon General, involving* an estimated cost of $42,000,000. Actually, fifty projects have been approved for construction totalling $34,730,000, an average of about $700,000 for each facility. There was concern in the beginning as to whether the facilities would be placed in the areas where they were most needed, but the early projects have been satisfactory in that respect. The state and territorial health officers' organization recommended that Congress be asked to provide needed funds and to expand the authorization.

. The final steps in the preparation of a state plan are of considerable interest. Public hearings are held before the state plan is approved after the state has decided on its various hospital areas and how many beds *they are entitled to; these matters are* put before all concerned in open meetings which usually have been well attended and have been quite acicable.

One worry is the continuing increase in costs, which may make project estimates of the present or of six months ago out of date when the time comes to allot a contract. The federal contribution of one third can be increased by a supplementary allotment, but the state or local area will have to meet the costs.

Dr. Dearing showed the Committee a booklet entitled "The Hospital and Your Community," which has just been published by the Division of Hospital Facilities of the Federal Security Agency in an effort to stimulate interest.

Discussion on the Hospital Survey and Construction Program was as follows:

Mr. Davis: The high cost involved is one of the principle difficulties encountered at present. At a meeting of the Rural Health Subcommittee of the Federal Hospital Council about a week ago the program was discussed at some length. Following are some reasons for the high costs: Labor in the building industry is about 38 per cent as efficient as before the war. Prevailing wages in the district must be paid in order to get federal assistance; the Department of Labor takes the highest prevailing wage in the state as the standard, and that is applied in small areas in the rural parts of the state. The problem of the local community's raising enough money is serious and is delaying construction programs. Because of increased costs, these communities must raise twice as much as they planned to raise. It is a question whether or not the poorest communities, even with *the generous assistance of the federal government*, would be able to raise two thirds or the cost. North Carolina and, I think, Mississippi have *appropriated* state funds. It is possible that we shall not get hospital facilities under this program as at present outlined in those poorest *areas where the need is greatest.*

Dr. Dearing: The State and Territorial Health Officers Association recommended (1) that the federal government be permitted to provide the cost of administration by the state agency becouse state funds in many instances are not adequate and (2) that the law be amended to permit the states which have not enacted enabling legislation by July 1, 1948, but which will pass it later, to come under the benefits of the act.

Dr. Sensenich: If we are going to seek methods of making the program more effective, it is important to know what is blocking it now. It might be of interest to have that information, because local medical societies should properly stimulate interest where the program has bogged down.

Dr. Henderson: It failed in Kentucky for some technical reason but probably will be approved in January or February 1948.

Dr. Bierring: In Wyoming the enabling act was opposed by the state medical society, and in Kentucky it failed or was not considered by the last state legislature.

THE NURSING PROGRAM

The Chairman asked Dr. Lull to inform the Committee regarding the work of the American Medical Association Committee on Nursing Problems.

Mr. Davis then stated: We in the hospital group want to compliment Dr. Thomas P. Murdock, chairman of the Committee on Nursing Problems, on the very fine way in which he conducted the meeting of his committee, *mentioned by Dr. Lull,* which some of us present today had the privilege of attending. Six or eight months ago the American Hospital Association became worried about the way that the medical profession and the *nursing profession* and the hospitals were all contending with each other in the public press. Articles appeared in which hospitals were blamed for exploiting the nurses, etc., and we suggested that there be a conference of five representatives from each group—the nurses, the physicians and the hospitals. The American Medical Association in the meantime had appointed its Committee on Nursing Problems, and that committee at the *meeting in November decided to recommend that the American* Medical Association be represented in the proposed conference. We in the hospital field hope that the conference of fifteen representatives, going along at the same time with this national study, will be in position to bring out a concrete program for nursing education and nursing service in the future that all of us can endorse.

RURAL MEDICAL SERVICE

Dr. Mulholland presented the following report:

The Committee on Rural Medical Service has participated in two regional conferences organized by the Council on Medical Service of the American Medical Association, one of which was held in Atlanta, Ga., and the other in ..ew Orleans. The Committee has received reports of *activities of rural health committees from forty-five states and Hawaii.* It is obvious that the information with respect to rural health is slowly but surely infiltrating the state medical associations. The deans of the medical schools were asked to send to our Committee any information they had with reference to the activities of their schools in regard to rural health. As a result, it has been found that five medical schools provide scholarships for students who will promise to practice in rural areas. Som cof the schools have preceptorships for senior students, who are sent out for practical experience with a rural physician. A good many have or will have *coordinated, correlated internships in rural hospitals*, and it is hoped that this will help the problem of general practice. Some of the *schools are including courses taught by general practitioners.* The program of the National Conference on Rural Health, to be held in Chicago February 6 and 7, is now in print. It has been prepared with the cooperation of the American Academy of Pediatrics. Some two thousand invitations to attend the conference have been sent to farm groups and to congressmen.

Dr. Evans spoke as follows on the matter of scholarships for students who will *promise to* practice in rural areas:

One trouble with the scholarship plan is the difficulty of asking a boy to commit himself before he really knows what medicine is. Certainly that became evident in the experiment of the Commonwealth Fund. Then, there is the problem of the physician going into the smaller communities and, while they had had a good hospital experience of two years or more, nonsurgical primarily, wanting to do surgery. Many of those who benefited from the Commonwealth Fund scholarships served their three years and went back into urban life. Another real difficulty is finding a way to help *the right person to get a medical education. I personally* feel that any help given to enable young physicians to practice in rural areas should *come primarily* in the graduate eriod. It is not easy to ask a student in the undergraduate period to commit himself to a future career. What might be done in the graduate period, I do not know. There have been several suggestions; certainly the attempt being made in Colorado, where they are setting out on a graduate training program for the general physician, is good. It will be interesting to see how the various state plans work; it is obvious that something of that nature ought to be tried, but I hope they will not all follow the same pattern.

THE WORLD MEDICAL ASSOCIATION

Dr. Henderson presented information with respect to the World Medical Association.

GRADUATE EDUCATION FOR MEDICAL OFFICERS

Dr. Irons presented the following report:

Dr. Sensenich and I went to Paris with Dr. Henderson and Dr. Bauer *not only as alternate representatives of the* American Medical Association to the organization meeting of the World Medical Association but also as an *informal mission* ,with Dr. Henderson, to investigate the opportunities for professional experience of medical officers in the American zones of occupation.

A Conference with the Surgeons General of the Army and Navy was held some time ago, and at Atlantic City, N. J., in June there was a meeting with the Secretary of War and the Assistant Secretary of the Navy. One of the problems of the Army is that the United States must maintain troops in Europe for a number of years; this will require medical officers, who will come largely from the younger group. At present, in some regions in the occupied zones there is a good deal of unhappiness among the younger medical officers, and it was felt that if by some means we could help the Surgeon General to improve the educational *opportunities* which these young men will have, the European service might be made attractive to young officers.

This was an informal mission undertaken with the approval of the Secretary of War and the Surgeon General of the Army. We were not an inspection group but merely wanted to find out what the opportunities are and what we could do to help. We received most helpful and cordial cooperation from all medical officers and from line officers as well. General Noyes, chief surgeon, European theater of operations, and all his officers were wonderfully cooperative. General Hayes in the Austrian Command already has a program in operation, and this has been helpful to his younger medical officers. The program was outlined by the three of us, Dr. Sensenich, Dr. Henderson and myself. We sent a memorandum to the Surgeon General and also to the Council on Medical Education and Hospitals. It will require a good deal of administration, care and thought, but we believe that the opportunities for educational advancement in universities such as those of Vienna, Heldelberg and Berlin will be developed so that the younger men, while on duty, can get further medical education of a type for which we ourselves had had to pay out money.

Colonel Robinson read the following statement on the Medical Department plan for supervised professional experience in the United States occupation zone in Germany:

I am sure that you gentlemen are well acquainted with the shortage of professional personnel in the Army Medical Service. This shortage is greatest in respect to the number of men who are qualified to perform the services of experts in the various special fields. In order to overcome this shortage the Surgeon General has been forced to rtain a large number of partially qualified experts in the United States for the purpose of completing their formal training. Thus it has been necessary to staff the hospitals in foreign theaters with young medical officers who are the product of the Army Special Training program. This lamentable situation will continue to exist for eighteen to twenty-four months unless some solution can be devised. It is believed that the situation may be improved somewhat by the provision of opportunity for graduate professional training and experience in this area. With this in mind General Bliss requested Drs. Elmer L. Henderson, R. L. Sensenich and Ernest E. Irons, who were visiting this area in connection with the organization of the World Medical Association, to investigate the possibilities of establishing graduate medical training in our Army hospitals. These gentlemen made a very thorough study and rendered a comprehensve report. I would like to take this opportunity to thank Drs. Irons, Henderson and Sensenich for this valuable service. In addition Drs. Irving Wright and Edmund Horgan spent a month in surveying the medical service of this theater and submitted certain recommendations regarding the possibilities of such a program.

After a thorough study of these reports and consultations with Dr. Byrl Kirklin and Dr. Frode Jensen, who was formerly associated with the Council on Medical Education and Hospitals, the Surgeon General has decided on the following plan:

1. In order to obtain a higher type of experts for this area opportunities will be made available for persons who have completed their formal training requirements to obtain supervised experience in the fields of internal medicine, general surgery, orthopedic surgery, obstetrics and gynecology, pediatrics, psychiatry and radiology at selected hospitals. It is not believed to be possible to fulfil the requirements for approved formal training in each specialty at these hospitals. However, supervision may be provided by means of visiting consultants in these specialties, who will volunteer for service in Germany for periods of at least one month and who will thus be able to visit each of the selected hospitals at frequent intervals. It is hoped that we shall be able to maintain at least one consultant in each of these fields in Germany at all times. A number of outstanding men have already volunteered. From the previously mentioned reports it appears that there is adequate clinical material available for the program. The specialties named are those in which the needs for qualified experts are most critical.

A few residents who are completing their training in January and July have signified their interest in these opportunities. Such persons will be commissioned in the Medical Corps Reserve with the rank commensurate with their age, training, experience and previous military service. When commissioner they will be ordered to active duty for periods of one, two or three years and assigned to duty in their specialty at the place of their choice.

When fully developed, the program will be made known to the Council on Medical Education and Hospitals of the American Medical Association and to the Specialty Boards concerned. Full data on each hospital together with the amount of supervisio nin each case will be provided. Every effort will be made to have these hospitals registered with the American Medical Association. It is hoped that this arrangement will meet with the full approval of these agencies, so that those who take advantage of these opportunities will unquestionably receive credit for the time they spend in Germany toward the limited practice requirements for admission to their examinations.

Providd this plan is successful and we are able to pursuade these men to remain at their hospitals for sufficient length of time, we shall then consider the development of a formal training program. Since most of the Specialty Boards require five days of teaching service per week by Diplomates of their respective boards, it is obviously impossible to establish formal training in Germany at the present time. The large majority of Army Board Diplomates must be utilized within the program being conducted in the United States in order to maintain this program at the highest possible educational level. I sincerely request the cooperation of everyone present in support of this program, so that we may render an adequate medical service to our Armed Forces and their dependents in the European theater of operations.

Dr. Sensenich said that an attempt had been made to build up a similar program for the Navy, but that the Navy's problem is much different; he believed that an interest might be built up in medical careers in the Army and Navy so that service will be more attractive.

OUTBREAKS AMONG THE NEWBORN IN HOSPITALS

Mr. Davis, who had requested that the subject of outbreaks of diarrhea among the newborn in hospitals be placed on the agenda, offered the following statement:

This is a problem that is giving hospitals great concern; statements have appeared in the newspapers to the effect that thousands of babies are dying in hospitals from diarrhea; a rather rough article was recently printed in *Look Magazine.* Some of the criticism possible is justified. In Michigan five or six years ago it was thought that we were on the trail of the bug that causes diarrhea, but the cause of infant diarrhea has never been found. An outbreak at St. Lawrence Hospital in Lansing caused the state health department to interest itself, and I think that it has been pretty well established from that deparmen's investigation that the infection was right there in the hospital itself. I suggested that perhaps what was discovered might be useful and that the national health organizations might bring out joint statements as to what has been discovered about the prevention and control of the disease. The report on the Lansing outbreak is being written up in a series of articles to appear in the journal of the American Hospital Association. A joint committee of the American Hospital Association and the American Public Health Association is studying the matter, but I think we need greater cooperation from the medical profession and the public health authorities. I am telling you about it now in the hope that before very long this Joint Committee might make recommendations whereby better support could be obtained from the medical profession.

WASHINGTON LETTER

Senator Langer Would Compare Nation's Expenditures on Animals and Human Beings

Sen. William Langer, Republican of North Dakota, has proposed a comparative study be made of the amount of money the federal government spends on the health of hogs, cattle and other livestock and the total spent on human beings.

Veterans Administration Staff Cuts Won't Affect Medical Divisions

Veterans Administrator Carl Gray, in announcing that some 8,500 of the agency's 200,000 personnel would be released before July 1, stated that no reductions would be made in the medical divisions. He explained that the staff must be cut to stay within the $6,100,000,000 budget recommended for the fiscal year of 1949 by President Truman. Mr. Gray informed his assistants by letter that the reduction is planned "on the assumption that the Congress will not appropriate in excess of budget recommendations."

Medical Records of Veterans to Be Used in Study of Rare Diseases

Dr. Paul B. Magnuson, medical director, Veterans Administration, announced that medical records of more than 100,000 veterans will be used in research studies on the causes and cures of rare diseases. The project will be directed by Dr. Edward Harvey Cushing, research director of the agency, and will go beyond hospitalization to determine cause of relapses and other after-effects. All medical records will be guarded. Under way now is a program of research on heart disease at Mount Alto Hospital, and Dr. Winfred Overholser, superintendent, St. Elizabeths Hospital, is directing a study on psychoneuroses at George Washington University Medical School. There are thirty-five general research laboratories in operation now in class A medical schools, and the agency plans to have such laboratories in all fifty-four veterans' hospitals, Dr. Magnuson stated. Dr. Harvey J. Tompkins, who has been with the agency since 1935, has been appointed head of its neuropsychiatric service.

HEALTH APPRAISAL OF SCHOOL CHILDREN

A pamphlet outlining standards for determining the health status of school children is now being distributed by the Bureau of Health Education of the American Medical Association.

The brochure is entitled "Health Appraisal of School Children" and is a report of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association. Recommendations as to how the teacher and the nurse may aid the physician with nonmedical portions of the examination are made. Suggestions regarding periodic medical examinations, special examinations and health inspections are also given. The material was edited by Dean F. Smiley, M.D., and Fred V. Hein, Ph.D., of the Bureau of Health Education Staff.

A complimentary copy will be sent to physicians, teachers and public health workers on request.

Coming Medical Meetings

Alabama, Medical Association of the State of, Mobile, April 15-17. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association for the Study of Goiter, Toronto, Can., King Edward Hotel, May 6-8. Dr. Thomas C. Davison, 478 Peachtree St.N.E., Atlanta, Ga., Secretary.

American Association of Anatomists, Madison, Wis., April 21-23 Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Industrial Physicians and Surgeons, Boston, March 28-April 4. Dr. Frederick W. Slobe. 28 E. Jackson Blvd., Chicago 4, Secretary.

American Association of Plastic Surgeons, Boston, May 6-8. Dr. W. H. Steffensen, 1810 Wealthy St.S.E., Grand Rapids, Mich., Secretary.

American Broncho-Esophagological Association, Atlantic City, Chalfonte-Haddon Hall, April 7-8. Dr. Paul H. Holinger, 700 N. Michigan Ave., Chicago 11, Secretary.

American College of Physician, San Francisco Civic Auditorium, April 19-23, Mr. E. R. Loveland, 4200. Pine St., Philadelphia 4, Secretary.

American Dermatological Association, Coronado, Calif., April 26-29. Dr. Harry R Foerster, 208 E. Wisconsin Ave., Milwaukee, Secretary.

American Federation for Clinical Research, Atlantic City May 4. Dr. John S. LaDue, 139 E. 36th St., New York 16, Secretary.

American Gastro-Enterological Association, Atlantic City, Claridge Hotel, April 30-May 1. Dr. Dwight L. Wilbur, 655 Sutter St., San Francisco, Secretary.

American Laryngological Association, Hot Springs, Va., April 14-15. Dr. Louis H. Clerf, 1530 Locust St., Philadelphia 2, Secretary.

American Laryngological Rhinological and Otological Society, Atlantic City, April 7-9, Dr. C. Stewart Nash. 277 Alexander St., Rochester, N. Y., Secretary

American Orthopsychiatric Association, New York, Hotel Commodore, April 12-14, Nina Ridenour, Ph.D., 1790 Broadway, Rm. 916, New York 19, Secretary.

American Otological Society, Hot Springs, Va., April 12-13. Dr. Gordon D. Hoople, 7qe E. Genesee St., Syracuse 2 N. Y., Secretary.

American Physiological Society, Atlantic City, March Atlantic City, March 15-19. Dr. Maurice Visscher, University of Minnesota, Minneapolis 14, Secretary.

American Society for Clinical Investigation, Atlantic City, Haddon Hall May 3. Dr. Eugene A. Stead Jr., Duke Hospital, Durham, N C., Secretary.

American Society for Experimental Pathology, Atlantic City, March 15. Dr. Frieda S. Robscheit-Robbins, 260 Criddenden Blvd., Rochester 7, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 14-19 Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

Arkansas Medical Society, Little Rock, Robinson Auditorium, April 15-17. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

American Society for Research in Psychosomatic Problems, Atlantic City, May 1-2- Dr. Eugene Ferris, 714 Madison Ave., New York 21, Secretary.

American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.

American Student Health Association, Detroit, Hotel Statler, May 7-8. Dr. George T. Blydenburgh, Ohio Wesleyan University, Delaware, Ohio. Secretary.

Association of American Physicians, Atlantic City, May 4-5. Dr. Henry M. Thomas Jr., 1201 N. Calvert St. Baltimore 2, Secretry.

California Medical Association, San Francisco, April 11-14. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8. Secretary.

Connecticut State Medical Society, Fairfield, April 27-29. Dr Creighton Barker, 258 Church Street, New Haven, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18. Dr. Glen D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Federation of American Societies for Experimental Biology, Atlantic City, March 15-19. Dr. William H. Chambers. Medical Division, Army Chemical Center, Maryland, Secretary.

Florida Medical Association, St. Augustine, Ponce de Leon Hotel, April 11-14. Dr. Robert B. McIver, 111 W. Adams St., Jacksonville, Secretary.

Georgia, Medical Association of, Atlanta, April 27-30. Dr. Edgar D. Shanks, 478 Peachtree St. N.E. Atlanta, Secretary.

Hawaii Territorial Medical Association, Honolulu, May 6-9. Dr. Harry L. Arnold Jr., 510 S. Beretania St., Honolulu 53, Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Louisiana State Medical Soceety, Monroe, April 12-14. Dr P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 27-28. Dr. George H. Yeager, 1211 Cathedral St., Baltimore, Secretary.

Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3. Exec. Secretary.

Nebraska State Medical Association, Lincoln, Hotel Cornhusker, May 3-6. Dr. R. B. Adams, 416 Federal Securities Bldg., Lincoln 8, Secretary.

New England Dermatological Society, Boston, April 14. Dr. G. Marshall Crawford, 1180 Beacon St., Brookline, Secretary.

New Jersey, Medical Society of Atlantic City, Haddon Hall, April 26-29. Dr. Earl LeRoy Wood, 315 W. State St., Trenton, Secretary.

North Carolina, Medical Society of the State of. Pinehurst, May 3-5. Dr. Roscoe D. McMillan, P.O.Box 232, Red Springs, Secretary.

Northern Tri-State Medical Association, Findlay, Ohio, April 13, Dr. Don F. Cameron, 247 W. Berry St., Ft. Wayne, Ind., Secretary.

Ohio State Medical Association, Cincinnati, Netherland Plaza Hotel, March 30-April 1. Mr. C. S. Nelson, 79 E. State St., Columbus 15, Secretary,

Southeastern Surgical Congress Hollywood, Fla., Hollywood Beach Hotel, April 5-8. Dr. Benjamin T. Beasley, 45 Edgewood Avenue S. E., Atlanta 3, Ga., Secretary

Southwest Allergy Forum, Oklahoma City, April 5-6. Dr. Fannie Lou Leney, 1200 N. Walker St., Oklahoma City, Secretary.

Tennessee State Medical Association, Nashville, April 13-14 Dr. W M. Hardy, 706 Church St. Nashville 3. Secretary.

Texas, State Medical Association of, Houston, Rice Hotel, April 26-29. Dr. Harold M. Williams, 1404 W. El Paso St. Fort Worth, Secretary.

United States-Mexico Border Public Health Association, Laredo, Texas and Nueva Laredo, Mexico, March 20-22. Dr. M. F. Haralson U.S. Court House El Paso, Texas, Secretary.

Western Section American Urological Association Victoria, B. C. Empress Hotel April 19-21. Dr. Adolph A. Kutzmann, 1930. Wilshire Blvd., Los Angeles, Secretary.

Medical Legislation

STATE LEGISLATION

Arizona

Bill Introduced.—S.33-xxxxx proposes to abolish various state examining boards including the board of examiners in the basic sciences, chiropody, chiropractic, dentistry, medical practitioners, naturopathic practitioners, nurses and osteopaths, and to vest the functions and duties of such boards in the secretary of state. The secretary of state, according to the proposal, would be authorized to establish a division of business and professional pursuits to perform the duties previously performed by the abolished boards.

Kentucky

Bills Introduced.—S. 161 proposes to provide means for providing medical scholarships at the University of Kentucky and other eligible instituions.
Kentucky and other eligible institutions. H. 302 proposes the creation of a division of medical and surgical hospitals and related services in the department of health and authorizes such division to be the state agency to accept funds from the federal government in carrying out the provisions of its hospital construction act.

Bills Passed.—S. 162 passed the senate February 25. It proposes to prohibit the handling, sale and distribution of barbiturates except on the written prescription of a practitioner licensed to prescribe and administer barbiturates, with certain stated requirements relating to pharmacists and wholesale dealers in the drug. S. 197 passed the senate February 25. It proposes the creation of a division of medical and surgical hospitals and related services in the department of health and authorizes such division to be the state agency to accept funds from the federal government in carrying out the provisions of its hospital construction act.

Mississippi

Bills Introduced.—H. 533, to amend the hospital construction act, proposes authorization for operating and equipping health centers or health departments in the various municipalities of the state. S. 358 proposes an appropriation to the Mississippi commission on hospital care for the purpose of contributing to the building, erecting and equipping of a teaching hospital in the school of medicine of the University of Mississippi.

Bill Passed.—H. 423 passed the house February 25 It proposes the creation of a four year medical school as a department of the University of Mississippi, which shall be operated as a class A medical school in accordance with the Council on Medical Education and Hospitals of the American Medical Association.

New Jersey

Bill Introduced.—A. 255 proposes the creation of a board of examiners in medical technology, which is defined to be the science, art or technic of performing any laboratory test or examination on or of the blood, blood serum, feces, urine, sputum, exudates, transudates, organ contents or any byproducts thereof, from the human body, living or deceased; when the test or tests shall be used either directly or indirectly as an aid in the care or treatment of diseases, abnormal or injured organs of the human body

New York

Bill Introduced.—A. 2348, to amend the public health law, proposes the creation in the department of public health of a commission to be known as the New York state health commission. Some of the proposed duties which would devolve on this commission are: (1) to formulate and execute a comprehensive, statewide plan designed to protect and improve the health of the people of the state; (2) to erect and maintain health centers providing additional hospital and outpatient facilities where needed; (3) to establish state scholarships on a competitive basis in medical schools, and (4) to provide basic financial assistance, not to exceed $2,000 per annum for a three year period, to qualified physicians who will agree to enter into private practice in rural areas, designated by the commission, lacking a sufficient number of qualified physicians to provide adequate health protection. A. 2368, to amend the education law, proposes to define x-ray diagnosis and to make the practice thereof the practice of medicine within the meaning of the medical practice act. A. 2416, to amend the public health law, proposes to make it the duty of every physician to give notice to the health officer of his respective county, city, town or village of every case of cerebral palsy under his care. S. 2467, to amend the education law, proposes that after July 1, 1949 medical students performing clinical clerkships or similar functions in a legally incorporated hospital shall be exempt from the provisions of the medical practice act.

Virginia

Bills Introduced.—H. 119 and S. 102, to amend the law relating to chiropractors and naturopaths, propose that any such person who received a temporary license to practice until Dec. 31, 1949 may be granted a license to practice by passing the examination required of chiropractors and naturopaths without taking the examination given by the special board of examiners in basic science. H. 439 proposes to require every practicing medical doctor to obtain a revenue license. S. 192 proposes to authorize the use in any criminal prosecution relating to drunken driving of the results of chemical analyses of the defendant's blood, urine, breath or other bodily substance. S. 199 proposes that children born as the result of artificial insemination shall be considered the same as legitimate children for all purposes, if the husband of the mother consented to the operation. S. 221, to amend the law relating to naturopaths, proposes that any person now licensed to practice naturopathy until Dec. 31, 1949 who is now practicing and has been practicing naturopathy in the state for at least five years shall be given a full license to practice without further examination and without any limitation as to time or period.

Bills Passed.—H. 354 passed the house February 27. It proposes to make it unlawful for any physician, dentist or optometrist to practice his profession as a lessee of any commercial or mercantile establishment or to advertise, either in person or through any commercial or mercantile establishment, that he is a duly registered practitioner and is practicing or will practice medicine, dentistry or optometry as a lessee of any such commercial or mercantile establishment. S. 105 passed the senate February 16. To amend the medical practice act, it proposes, among other things, to exempt therefrom interns and residents in legally established and licensed hospitals provided their practice is confined strictly to persons who are bona fide patients within the hospital or who receive treatment and advice in an organized outpatient department of the hospital to which ambulant patients regularly come for professional services rendered under supervision of licensed members of the hospital staff. Such interns and residents, however, must have completed successfully the preliminary academic education required for admission to examinationsggiven by the board in their particular field of practice or hold a valid license issued in a state maintaining standards acceptable for reciprocity with the state of Virginia. No graduate of a substandard medical school may be so employed except under particular cases. S. 106 passed the senate February 16. To amend the medical practice act, it proposes to authorize the state board of medical examiners to suspend or revoke the certificate of a physician who has been the legally responsible head of a hospital the license of which has been revoked because of illegal practice or conduct or practices detrimental to the welfare of a patient therein by the state board of health. S. 107 passed the senate February 16. It proposes to require the annual renewal of certificates to practice medicine, homeopathy, osteopathy, chiropractic, naturopathy or chiropody on or before June 30 of each year.

ARMY

PREVENTIVE MEDICINE SPECIALTY BOARD

An Interim Board of Preventive Medicine under the joint auspices of the Surgeon General of the Army, Navy and Public Health Service has been established. According to the announcement, the board was formed to set up certification requirements for medical officers seeking to qualify as specialists in the field. Final approval and nationwide acceptance of the board's requirements will result in the elevation of preventive medicine to a specialty status. The members of the board are: Ernest L. Stebbins, director, Johns Hopkins University School of Hygiene and Public Health, chairman; Wilton L. Halverson, California State Director of Public Health; Harry S. Mustard, New York City Health Commissioner; Thomas Francis Jr., University of Michigan School of Public Health; Gaylord W. Anderson, director, University of Minnesota School of Public Health; Hugo Muench, assistant dean, Harvard School of Public Health; James Crabtree, deputy surgeon general, U. S. Public Health Service; Col. Tom F. Whayne, chief, Army's Preventive Medicine Division, and Capt. Otto L. Burton, chief, Preventive Medicine Division of the Navy.

COURSE IN PHYSICAL RECONDITIONING

The Surgeon General has announced a new eight weeks' course of instruction in physical reconditioning to be conducted at the Brooke Army Medical Center, Fort Sam Houston, Texas, beginning April 26, 1948. The purpose of this course is to qualify officers to activate, organize and administer programs of physical reconditioning. Officers qualifying for the course will report on April 20 or 21. The course may be attended by regular Army officers, organized reserve or national guard officers, or officers of the Army Medical Department who will have a minimum of one year to serve in the Army after completion of the course. Such officers must be below the grade of lieutenant colonel and must have had at least two years' experience in physical education or have completed a two year college course in which they majored in physical education. Under certain conditions, officers may attend this course prior to entering on a competitive tour for regular Army commissions in the medical service corps. First, they must be qualified for entrance on a competitive tour under provisions of medical circulars 101 or 210, 1947, and second, they should have had experience in the fields of physical reconditioning or corrective physical rehabilitation or be a graduate of an approved course in physical education. Applications must reach the Surgeon General not later than March 20.

ARMY AWARDS AND COMMENDATIONS

Colonel Herrman L. Blumgart

Col. Herrman L. Blumgart of Boston has been awarded the Legion of Merit. The citation reads as follows: "Colonel Blumgart performed exceptionally meritorious service from May 1943 to December 1944. As Medical Consultant, Second Service Command, he used his high professional attainments and administrative ability to promote the highest quality of diagnosis and care of patients in all medical installations within the Command. His constant appraisal of the ability and training of medical officers resulted in the use of these officers to the fullest degree and facilitated the personnel organization in opening new installations. During certain emergencies that arose within the Command, Colonel Blumgart personally supervised the care and treatment of the patients involved and was instrumental in the saving of many lives." A second citation reads as follows: "Colonel Herrman L. Blumgart performed exceptionally meritorious service as Medical Consultant, in the India-Burma and China theaters, from January to October 1945. His keen judgment in the evaluation of the professional capabilities of the medical officers under his jurisdiction, as well as his profound knowledge of the medical problems of both theaters, enabled him to carry out measures that revitalized the medical service. The notable accomplishments achieved in these theaters are due in a large part to the professional ability, loyalty and untiring devotion to duty of Colonel Blumgart." Dr. Blumgart graduated from Harvard Medical School in 1921 and entered military service in February, 1943.

Captain Robert G. Demos

Capt. Robert G. Demos, M. C., formerly of Nashville, Tenn., has been awarded the Army Commendation Ribbon. The citation reads as follows: "Captain Demos, while serving as chief, Obstetrical and Gynecological Section, Surgical Service, Oliver General Hospital, distinguished himself by meritorious performances in prenatal, obstetrical and postnatal care from January to October 1947, a period without a single maternal death. During this period, 3 premature babies weighing less than 3 pounds (1,361 Gm.) at birth were skilfully studied, nursed, fed and raised to normal development. The survival of one 30 ounce (850 Gm.); five and one half months prenatal infant, the smallest ever born in a U. S. Army Hospital to survive, is a single instance of his accurate professional planning. This accomplishment was the direct result of continuous professional study and application of modern methods, constant devotion to duty and above all, an untiring energy to respond immediately to the call of any patient." Dr. Demos graduated from the University of Tennessee Medical School, Memphis, in 1944 and entered military service in April, 1946. He will leave the service in March to engage in practice in Chattanooga, Tenn.

LIBRARY ACQUIRES THE "GREAT HERBAL"

The Army Medical Library, Washington, D. C., has acquired a nineteenth century edition of Li Shihchen's Chinese "Great Herbal" (Pen Ts'ao Kang Mu) in fifty-two volumes. The original of this work was published in 1596 shortly after the death of its compiler, who is said to have labored on it for almost thirty years. Although commonly translated as "The Herbal," it is actually a complete materia medica. Three of its supplementary volumes consist entirely of fine wodocuts illustrating the animals, plants and minerals which form the basic substances of all drugs described in the work itself. This work represents a critical study of 1,578 prescriptions contained in earlier works, to which the author added three hundred and fifty-eight new drugs.

PERSONALS

Col. John M. Caldwell, M. C., chief of neuropsychiatry, Consultants Division, Surgeon General's Office, has been appointed clinical professor of psychiatry and Lieut. Col. Stephen C. Sitter, M. C., assistant chief of neuropsychiatry, Consultants Division, associate professor of psychiatry at Georgetown University, Washington, D. C.

Dr. William S. Middleton, dean, University of Wisconsin Medical School, Madison, has returned to active duty as a colonel of the medical corps for a period of five weeks to act as a medical personnel consultant in the Surgeon General's Office. Colonel Middleton during the war was chief medical consultant to the chief surgeon in the European theater of operations.

Miss Elsa Schneider has been appointed assistant specialist in health and physical education on the staff of the U. S. Office of Education, Federal Security Agency, Washington, D. C. Miss Schneider was formerly with the State Department of Public Instruction in Illinois and was assistant state director of health, physical education and safety for four years.

Dr. Theodore R. Meyer, Sag Harbor, N. Y., has been appointed chief of the medical research and training section of the public health branch, Office of Military Government in Germany. Dr. Meyer was formerly director of the Van Buren County health department in Michigan and of the St. Louis county department in Missouri previous to entering the medical service of the Navy in the recent war.

VETERANS ADMINISTRATION

HOSPITAL AT LITTLE ROCK

The veterans' hospital at North Little Rock, Ark., has been designated as a plastic surgery center, a neurosurgery center and a neuropsychiatric tuberculosis cented. It is located on the bank of Arkansas River several hundred feet above the business district and less than 2 miles from the city. The hospital is so organized that it functions as a small community with itself, closely affiliated with the larger communities in surrounding cities and states. Members of the staff have become thoroughly interwoven into the medical structure of surrounding professional societies, they participate in the affairs of the medical school, and civilian medical authorities participate in professional activities in the hospital. Consultants have been selected among the leading practicing physicians and from the staff of the local medical schools. A residency training program has been developed and at present eight residents and six staff members are actively participating. According to the neuropsychiatry division of the Veterans Administration, this hospital has more than 1,400 chronically psychotic veterans, 70 per cent of whom are of rural origin and the treatment of whom is determined by their environmental background as well as their physical and mental capacities. The hospital reservation comprises about 1,100 acres. The 260 acre farm owned and operated by the hospital produces an average of $3,700 worth of vegetables a year, a large amount of corn and wheat, and hogs which provide fresh pork throughout the year. Also entering into the care of patients are recreational and occupational facilities including shops of various kinds, athletic fields, a nine hole golf course, libraries and recreation halls. There are fifteen ward buildings and seventy-six other structures. The hospital has a bed capacity of 2,400.

RECLAMATION AND REPAIR OF MEDICAL EQUIPMENT

Nearly $2,800,000 of medical equipment consisting of x-ray machines, electrocardiograph equipment, anesthesia apparatus and the like has been repaired by Veterans Administration service and reclamation shops. The total cost of putting this equipment into usable shape has been estimated to be about 7.14 per cent of the value of the equipment. Costs of repair include salaries of repairmen, parts, electric power and lights and all other expenses that could be attributed to the repair service. In addition to repairs shop employees install new medical equipment in Veterans Administration hospitals, homes and regional offices at a saving of time and money. Repair work is carried on at supply depots in Somerville, N. J., Hines, Ill., Montgomery, Ala., and Wilmington, Calif., by a staff of repairmen who have between ten and twenty-five years' experience working with technical medical equipment.

RESEARCH PROJECTS

The Veterans Administration has thirty-five general research laboratories in operation in hospitals affiliated with class A medical schools. The Veterans Administration hopes that such laboratories will be established in all fifty-four veterans' hospitals which operate in conjunction with medical schools and in some of the nonaffiliated hospitals. In addition, six laboratories for radioisotope research and therapy will be established this year and three more next year. A cardiovascular research unit is in operation at the Mount Alto Hospital in Washington, D. C. Twenty hospitals are engaged in a broad investigation of the value of streptomycin therapy for tuberculosis. Two centers for exhaustive study of patients with sarcoidosis will be established. Other projects to get under way this year will be a study of vagotomy in the treatment of peptic ulcer and an evaluation of the usefulness of providing albumin treatment in hepatic diseases. Contracts for research on artificial limbs have been awarded to various universities, private industries and the National Academy of Sciences.

PERSONALS

Dr. Thomas J. Ready has been assigned as chief medical officer and Dr. Frank D. Thomas as chief of the outpatient medical service for the Pass-a-Grille regional area in Florida. Dr. Ready is a graduate of Georgetown University School of Medicine, Washington, D. C., and served in the Army Medical Corps during the recent war. Dr. Thomas is a graduate of Hahnemann Medical College, Philadelphia, and is a veteran of World War I.

Dr. Clarence R. Miller has been assigned as manager of the Veterans Administration Hospital at Jackson, Miss., to succeed Dr. J. Ralston Wells, who will be in charge of the Veterans Hospital at Dallas, Texas. Dr. Miller is a veteran of World War I, formerly served in the U. S. Public Health Service, and for many years has been in the Veterans Administration.

Dr. Robert A. Houston, Sunbury, Pa., has been appointed chief of medical services of the veterans' hospital at Lebanon, Pa., effective February 1.

E. Burns Geiger, formerly of Hagerstown, Md., has been appointed chief of the Pharmacy Division of the Veterans Administration Department of Medicine and Surgery. Mr. Geiger served in the Navy during the war and later became assistant to the chief of the Division of Pharmacy.

Dr. George S. Peters has resigned as chief of the Surgical Service at the veterans' hospital, Montgomery, Ala., and will enter private practice in that city.

Dr. David E. Quinn, formerly manager of the veterans' hospital at Oteen, N. C., has assumed his new duties as medical director of the Northwest Branch of the Veterans Administration with headquarters at Seattle.

Dr. Horace B. Cupp, for a long time on the staff of the Johnson City, Tenn. veterans' hospital, has been named assistant medical director for the Southeastern Branch of the Veterans Administration, which supervises fifteen hospitals and six regional offices in the five Southeastern states. Dr. Cupp served in the Army in the recent war in command of the 63d Station Hospital in Australia and later as commanding officer of a hospital ship.

Dr. James Van D. Nelson, who has been with the Veterans Administration since 1920 and whose recent assignment was at the hospital in Bay Pines, Fla., retired from government service in December.

Dr. Edward E. Johnston has resigned as manager of the Nichols Hospital at Louisville and will enter private practice at Elizabethtown, Ky. Dr. Leverett S. Woodworth has been appointed assistant to the clinical director at the Nichols Hospital. Dr. Woodworth was formerly superintendent of the Massachusetts Memorial Hospital, Boston.

Dr. Howell Brewer, manager of the rehabilitation hospital at Fort Thomas, has been transferred to the veterans' branch office at St. Louis. Dr. Brewer will direct the physical medicine program in the ten hospitals under supervision of the regional branch office.

HOSPITAL NEWS

The opening date for bids on construction of a five hundred and sixty-four bed addition to the neuropsychiatric hospital at **Lebanon, Pa., was extended, at the request of contractors, to February 10.**

The Chief of Army Engineers announced that the February schedule of the closing dates for general construction bids on veterans' hospitals includes the following six general hospitals: Albany, N. Y., 1,000 beds; Little Rock, Ark., 500 beds; Wilkes-Barre, Pa., 475 beds; Wilmington, Del., 300 beds; Altoona, Pa., and Beckley, West Virginia, 200 beds each. The February schedule also includes invitations to contractors to submit bids for general construction contracts on a 1,000 bed hospital at Newark, N. J., and a 200 bed hospital at Erie, Pa.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

COLORADO

Gengenbach Library.—A special library is being established in honor of Dr. Franklin P. Gengenbach, at the University of Colorado Medical Center, Denver, by the Rocky Mountain Pediatric Society. A gift of $250 to start the library was made by the society and other donors interested in pediatrics, and a special fund will be given each year to add new volumes. Dr. Gengenbach, one of the first pediatricians west of the Mississippi, has been practicing in Denver for forty-seven years.

Establish Premature Infant Center.—A Premature Infant Center has just been inaugurated at the University of Colorado Medical Center, Denver. Sponsored by the state department of public health, the state university and the Colorado State Medical Society, the program has been set up to provide facilities for the training of physicians, nurses and other personnel for the prevention and treatment of infant prematurity. The activities of the center are made possible by a grant from the U. S. Children's Bureau. Fifty of every thousand Colorado-born infants die in the first year of life, as compared with the national average of thirty-eight deaths per thousand live births. The medical supervision of the Premature Infant Center is the joint responsibility of the departments of pediatrics and of obstetrics and gynecology at the University of Colorado Medical Center. Premature babies born within a radius of 30 miles of the center may have the services of a special ambulance for transportation. Infants outside this area will be accepted if safe transportation can be arranged. The division of maternal and child health of the state department of health has made available several incubators for loan to facilitate premature infant care in other hospitals.

CONNECTICUT

Personal.—Leonell C. Strong, Ph.D., associate professor of anatomy at Yale, will go to Europe early this spring to lecture on cancer research in Belgian universities. Dr. and Mrs. Strong will be guests of the National Cancer Foundation in Belgium. He will also visit laboratories in Belgium and other nearby countries. Dr. Strong has been asked to lecture in Stockholm, Sweden; Copenhagen, Denmark; Amsterdam, Netherlands, and England. The professor and his wife also expect to attend the eighth International Congress of Genetics in Stockholm during July.

New Veteran's Placement Committee.—A Medical Advisory Committee of five physicians has been named by the Connecticut State Medical Society to aid in the occupational placement of disabled war veterans. Believed to be the first committee of its kind in the country, the group will furnish consultation on employment-medical problems to the veterans' employment division of the United States Employment Service, and to the Connecticut State Employment Service. Members of the committee are Drs. S. Bliss B. Clark, chairman, New Britain; Charles I. Solomon, Meriden; Arthur C. Unsworth, Hartford; Robert W. Nespor, Westport, and Russell V. Fuldner, New Haven.

Institute of Child Psychiatry.—Construction of a five story building to house an Institute of Child Psychiatry has been started on the campus of the Institute of Living in Hartford. The directors of the institute, one of the country's oldest hospitals for the treatment of mental and nervous diseases, have planned the project as the result of fifteen years of psychiatric treatment of adolescent and preadolescent children. Plans include a Parentorium, an original concept to furnish guidance for the parents of emotionally disturbed children. The project, it is estimated, will cost in excess of $150,000, of which more than $100,000 has been subscribed. A large part of this sum has come from members of the institute's own personnel. The new Institute of Child Psychiatry will contain classrooms, a gymnasium, shops, treatment rooms and other facilities. The ultimate capacity of the institute will be 66 children.

ILLINOIS

Fight Against Venereal Disease.—The Cook County Health Department has set up a program to eliminate venereal disease. Over 700 cases of syphilis were reported in suburban Cook County in 1947, the same number as in 1946, and a decrease from 652 to 526 was reported in gonorrhea cases. Five venereal disease clinics are operated by the health department and give about six hundred treatments monthly.

Chicago

Quine Library of Medical Sciences.—The Quine Library of Medical Sciences at the Chicago Professional Colleges of the University of Illinois has a total of 84,910 volumes and is now receiving 923 current journals. The present rate of growth is over 4,000 volumes annually. A special effort has been made to fill in files of foreign periodicals for the war years. With the exception of German journals, nearly complete sets of most of the foreign titles which continued publication during the war have been received. In addition about 300 volumes of French, German and Italian medical works have come in through the Library of Congress cooperative project for the acquisition of wartime publications.

University Orders Magnet for Cyclotron.—The University of Chicago's new giant cyclotron is to have a 4,140,000 pound magnet, to be delivered in July. The magnet will accelerate protons to a speed of some 160,000 miles a second. The institutes of radiobiology and biophysics will use the beam on the cyclotron, among other things, for studies on cancer research. A building to house the cyclotron is under construction.

Grants for Research.—The University of Illinois College of Medicine has received a nutrition fellowship grant of $3,500 from Swift and Company, Chicago, for a year's study of amino acids in the blood in disease. The project will be conducted by the department of surgery under the supervision of Dr. Tilden C. Everson. A grant of $7,920 from the Upjohn Company of Kalamazoo, Mich., will be used to evaluate the use of the pancreatic enzyme lipase A in the treatment of patients who have the symptoms of diarrhea due to pancreatic deficiency. The study will be conducted by the department of medicine under the direction of Dr. Michael H. Streicher. A research grant of $2,700 from Hoffmann-LaRoche, Inc., of Nutley, N. J., will be used for the study of a new sulfone product in the treatment of chronic ulcerative colitis. A grant of $1,500 from Ciba Pharmaceutical Products, Summit, N. J., will be used for the study of skin-sensitizing properties of a nicotinic acid derivitive, under the direction of Dr. Adolph Rostenberg, Jr.

LOUISIANA

Smith-Clark Eye Clinic.—The Smith-Clark Eye Clinic in New Orleans, opened January 2, is said to be the second clinic in the United States to be built and devoted exclusively to treatment of disease of the eye. No beds are provided for inpatients.

Dr. Jones Appointed Editor.—Dr. Philip H. Jones, New Orleans, has been appointed editor of the *New Orleans Medical and Surgical Journal* published by the Louisiana State Medical Society to succeed Dr. John H. Musser, who died Sept. 5, 1947. Dr. Jones obtained his medical degree from Tulane University of Louisiana School of Medicine, New Orleans, in 1920, being the third generation of his family to receive an M.D. from Tulane. As a Rhodes Scholar he obtained his Ph.D degree in pathology in 1924. He returned to New Orleans in 1925. He had served on the faculty at Tulane until he entered private practice in 1929, and in 1945 he was president of the Orleans Parish Medical Society.

MASSACHUSETTS

Hospital Granted Funds for Cancer Research.—The American Cancer Society has granted the Massachusetts General Hospital $100,000 for cancer research in addition to the $50,000 recently given to the hospital for similar research by the Damon Runyon Fund.

Director, of Division of Venereal Diseases.—Dr. Nicholas J. Fiumara, Boston, has received a permanent appointment as director of the division of venereal diseases of the Massachusetts Department of Public Health. Dr. Fiumara, a former navy medical officer, is a graduate of the Boston University School of Medicine, 1939, and the Harvard School of Public Health. He has been temporary director of the division of venereal diseases since April 1947.

Cutter Lecture on Preventive Medicine—Dr. William N. Pickles, medical officer of health, Aysgarth Rural District, Yorkshire, England, will deliver the Cutter Lecture on Preventive Medicine April 12 at 5 p. m. in Amphitheatre D of Harvard Medical School, Boston. His subject will be "Epidemiology in Country Practice." The lectures have been held since 1912. Physicians, students of medicine and public health and other interested persons are cordially invited.

MICHIGAN

Cancer Day Program.—The Genesee County Medical Society announces its third Annual Cancer Day Program, March 31, at Flint, in the Merliss Brown Auditorium at Hurley Hospital beginning at 10 a.m. The following program will be given:

Charles F. Branch, Chicago, Cancer of the Osseous System.
Richard H. Overholt, Brookline, Mass., Cancer of the Lung.
Allen O. Whipple, New York, General Principles of Cancer Management.
Alexander Brunschwig, New York, Extensive Surgical Procedures for Cancer.
Manuel M. Garcia, New Orleans, Role of Radiotherapy in Management of Cancer.

MISSOURI

Past Presidents' Banquet.—The annual banquet honoring past presidents of the St. Louis Medical Society will be held March 15 in the Gold Room of the Jefferson Hotel, St. Louis. Dr. Edward L. Bortz, Philadelphia, President of the American Medical Association, will speak on "Medicine's New Frontiers." Physicians, wives of physicians, and friends are invited.

NEW YORK

Scholarships in Sight Conservation.—Delta Gamma, national social sorority, has a $1,000 annual fund, from which smaller scholarship awards are available for preparation of those intending to become (1) orthoptic technicians, (2) teachers of children with partial vision or (3) specialists for blind preschool children. Any one wishing to specialize in these fields may be eligible for assistance. Application for a scholarship should be made to Mrs. Richard P. Miller, 39 West Jefferson Road, Pittsford, N. Y.

Pediatricians Meeting in Buffalo.—An area meeting of the American Academy of Pediatrics, will be held at the Hotel Statler, Buffalo, April 29 to May 2. The program includes papers on the following subjects: metabolic disturbances, the cardiovascular system, management of the child with chronic disease and the central nervous system. May 2 has been designated Clinical Day, when demonstration of cases will be made at Children's Hospital and Edward J. Meyer Memorial Hospital. The registration fee is $10. Those wishing to register ahead of time may send checks to Dr. Clifford G. Grulee, secretary-treasurer, American Academy of Pediatrics, 636 Church Street, Evanston, Ill.

New York City

Center for Emotionally Disturbed Children.—A center for the treatment of emotionally disturbed children will open at Adelphi College, Garden City, N. Y., this month on a fee schedule. The center has been approved by the Nassau County Medical Society, the Nassau County Board of Health and the medical advisory board of the college. The objectives are treatment of a limited number of emotionally maladjusted children referred by the schools and social agencies; research in the psychiatric treatment of maladjusted children; training of graduate students majoring in psychology, social work and education, and provision of clinical experience for a select group of physicians and graduate nurses interested in psychiatric treatment of children. The medical director will be Dr. John C. Thurrott, a practicing psychiatrist in New York City.

Lecture on Application of Science in Medicine.—David Rittenberg, Ph.D., associate professor of biochemistry at the Columbia University College of Physicians and Surgeons, will deliver the second lecture in the series on the application of fundamental sciences in medicine at the Jewish Sanitarium and Hospital for Chronic Diseases, Brooklyn, Wednesday, March 31, at 8:45 p.m. His subject will be "The Application of Nuclear Chemistry in Medicine."

Fellowships on Pathology of Tumors.—Through the W. T. Grant Foundation, fellowships on the pathology of tumors are available in the laboratories of Memorial Hospital for the Treatment of Cancer and Allied Diseases. Requirements are that a candidate shall hold appointment as assistant professor or instructor in a university department of pathology and that he shall be given a one year leave of absence with a guarantee that he may return to academic status after completion of the fellowship. These fellowships are designed for training of personnel of universities which have received government grants for establishment of correlated work in the teaching of cancerology. Students will have access to about 18,000 specimens per year and will attend conferences and follow-up clinics. Research may be undertaken as a minor portion of the program provided it forms a part of one of the research programs being conducted in the institution. The annual stipend of $5,000 may be supplemented by the university in any individual case. Application should be made to Dr. Fred W. Stewart, Memorial Hospital, 444 East Sixty-Eighth Street, New York 21.

Dr. Boggs Appointed Acting Dean.—The appointment of Dr. Robert Boggs, assistant dean of New York University College of Medicine, as acting dean of the New York Post-Graduate Medical School was announced March 1. Dr. Boggs received his M.D. degree from McGill University Faculty of Medicine, Montreal, Canada, 1933. During the war he was medical officer of the U.S.S. *Wichita* in the Pacific area and was also stationed at Columbia University and at St. Albans Naval Hospital. The Post-Graduate Medical School, incorporated in 1882, has a current annual registration of about one thousand, one hundred physicians and specialists. The Post-Graduate Hospital, located at 303 East 20th Street, has four hundred beds and is currently providing medical services in about one hundred thousand outpatient visits annually.

PENNSYLVANIA

Rheumatic Heart Clinic for Lawrence County.—The State Rheumatic Heart Clinic for Lawrence County, with Dr. John O. Woods, New Castle, medical director, was inaugurated January 28. All patients who have rheumatic fever are to be registered through their personal physicians, after which they may be given appointments for complete examinations with special reference to rheumatic heart disease. Diagnostic and consultation services are offered to patients under 21 years of age who have rheumatic heart disease. Information concerning a patient will be made available to his personal physician, who must request treatment before it will be given.

Philadelphia

Personal.—Alfred Z. Gilman, Ph.D., associate professor of pharmacology, Columbia University College of Physicians and Surgeons, delivered the annual Bernard Comroe Memorial Lecture February 6 at the University of Pennsylvania School of Medicine.

A Plaque for Dachshund Bozo.—The dachshund which has helped medical students at Jefferson Medical College of Philadelphia to learn the use of the bronchscope was recently honored with a plaque from the Dachshund Club of America. For four years Bozo has served medical students who wanted to familiarize themselves with the bronchoscopic method of removing buttons, pins, stones and other items from the throats of babies. Bozo's work is painless. He has a host of friends and can take real satisfaction in knowing that he has helped to save the lives of hundreds of children.

Naval Reserve Officers.—Civilian medical personnel interested in being associated with a U. S. Navy medical reserve division may obtain information through the Office of the Commandant, Fourth Naval District, Philadelphia. Capt. John G. Manley, U.S.N.R., has been assigned executive officer of the Volunteer Reserve Medical Division 4-3, Philadelphia; in addition, the following reserve medical officers on inactive duty have been assigned to this division: Comdrs. James E. Bowman, Martin P. Crane and Charles M. Thompson; Lieut. Comdr. Robert F. Sterner; Lieut. Carroll F. Burgoon, and Lieut. (jg) Karl C. Jonas.

TEXAS

Cancer Detection Clinic.—The Tarrant County Tumor Clinic for the detection and treatment of cancer has been established in Fort Worth with Dr. W. Porter Brown, director, and Dr. Helen Gottschalk, executive director. The clinic is open to the public every Tuesday morning; on any other day a patient may be seen by appointment.

Baylor Hospital Fund Oversubscribed.—The $1,000,000 Truett Memorial Fund, to which Dallas citizens contributed to help pay for a $4,000,000 expansion of Baylor Hospital, has been oversubscribed by about $50,000. The sum will be added to the $1,000,000 raised in 1943, the $1,000,000 contributed by the Baptist General Convention, in which Dr. Truett was a leader, and the $1,000,000 to be borrowed. The money is to be used to build a seven story, eight hundred bed hospital on the present grounds of Baylor Hospital in Dallas.

WISCONSIN

Nicholas Senn Memorial Hospital.—Use of his $300,000 estate for building a general hospital in Milwaukee to be known as the Nicholas Senn Hospital in memory of his father was requested in the will of Dr. Emanuel J. Senn, aged 78, who died Dec. 14, 1947. Dr. Nicholas Senn practiced in Milwaukee for many years before going to Chicago. He was former professor of surgery at Rush Medical College and chief of staff at

Presbyterian Hospital. The estate is to remain in trust, as provided by the will, for the benefit of Dr. Senn's widow for her lifetime.

Drs. Lincicome and Rasmussen Jr. Appointed to Faculty.—David R. Lincicome, Ph.D., assistant professor of parasitology at the University of Kentucky, Lexington, has been appointed assistant professor of parasitology in the department of microbiology at the University of Wisconsin Medical School, Madison. Dr. Lincicome received his master's degree from the University of Illinois in 1937 and his doctor of philosophy degree in parasitology from Tulane University of Louisiana, New Orleans, in 1941. Dr. A. Frederick Rasmussen Jr., formerly associated with the Army Medical Corps and Graduate Medical School at Walter Reed Hospital in Washington, D. C., has been appointed associate professor of microbiology and preventive medicine. He obtained his Ph.D. degree from the University of Wisconsin in 1941 and his M.D. degree in 1944. Following an internship, Dr. Rasmussen was a member of the Army Medical Corps. For the past two years he has been working chiefly in the fields of rickettsial bodies and viruses.

VIRGINIA

Spring Graduate Course in Ophthalmology.—The twenty-first annual Spring Graduate Course of the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, will be given April 5-10. *Among the guest speakers in ophthalmology will be Professor* Adalbert Fuchs, UNRRA-World Health Organization, Nanking - Shanghai, China; Drs. Conrad Berens, New York; Albert D. Ruedermann, Detroit; Edwin B. Dunphy, Boston; Trygve Gunderson, Boston; John M. McLean, New York, and Alston Callahan, Birmingham, Ala.

PUERTO RICO

Municipal Hospital Improvement Program.—A vast municipal hospital improvement program is under way in Puerto Rico with an appropriation of $793,000 voted by the insular legislature last year. A special construction agency has already completed construction of five new hospitals with a capacity of from sixteen to twenty beds each and is now nearing completion of new units for six other municipalities. New equipment will be purchased for all these units. In the city of San Juan, with an additional special appropriation amounting to $75,000, the following projects for the improvement of hospital facilities are being carried out: (1) addition to the Surgery Hospital in San Juan and (2) construction of a two story building for the Pathology Department. This building will consist of an autopsy room, a morgue and facilities for pathologic services. For the first time in the history of medical services in Puerto Rico forensic medical services will be provided in the municipal hospital of San Juan, when these improvements will be completed. The organization of this service is being carried on by the government of the city of San Juan and the insular office of the attorney general.

GENERAL

Meeting on Physical Medicine.—The spring session of the eastern section of the American Congress of Physical Medicine will meet at 2 p.m., Saturday, April 10, at Jefferson Medical College of Philadelphia. The program includes a symposium on the effect of physical inactivity and of exercise in the afternoon, and a roundtable discussion on low back pain and the sciatic syndrome in the evening at the Benjamin Franklin Hotel.

American National Red Cross Drive in March—The American National Red Cross will conduct its annual campaign this month to raise $75,000,000. During the past year, disasters totaled about three hundred and more than 300,000 persons were aided in emergencies that followed in their wake. In addition, there are 18,000,000 war veterans, a substantial segment of whom seek and require the services and assistance of the Red Cross, both on the chapter level and in government hospitals.

Examination of Orthoptic Technicians.—The annual examination of orthoptic technicians by the American Orthoptic Council will be conducted in September and October. The written examination will be nonassembled and will take place September 9 in certain assigned cities and offices under the proctorship of designated ophthalmologists. The oral and practical examinations will be October 9 in Chicago, just preceding the meeting of the American Academy of Ophthalmology and Otolaryngology. Application for examination will be received by the office of the secretary of the American Orthoptic Council, Dr. Frank D. Costenbader, 1605 Twenty-Second Street N.W., Washington 8, D.C., and must be accompanied by the examination fee of $25.

National Negro Health Week.—Health plans for the individual and the family will be emphasized during National Negro Health Week, April 4-11, sponsored annually by the Public Health Service of the Federal Security Agency. Participating communities will urge each Negro family to clean home and premises, check health habits, seek proper medical aid and obtain necessary corrective treatment. Negro children will receive physical check-ups at school and will learn the fundamentals of good health through health plays and contests. Special tribute will be paid to the founder of the Health Week movement, Booker T. Washington, whose April 5 birthday determines the time of the observance. More than 12,500 communities in thirty-six states and territories took part in the 1947 Health Week. The All-America trophy for the best Health Week and year-round program was awarded to Savannah-Chatham County, Georgia.

Board of Orthopaedic Surgery.—At its annual meeting in Chicago January 24, the American Board of Orthopaedic Surgery passed a resolution to increase the examination fee for Part II of the examination of the board from $35 to $50. This increase is now in effect, and candidates applying for Part II to be given in January 1949 are notified of this change. There is no change in the fee of $15 which is submitted with the application. The deadline for receipt of applications for Part II of the examination has been established as August 15. Correspondence and applications should be directed to the secretary of the board, Dr. Francis M. McKeever, 1136 West Sixth Street, Los Angeles 14. Checks should be made out to the American Board of Orthopaedic Surgery, Inc. Applications for Part I of the examination, to be given in the spring of 1949, must be received by the secretary not later than Jan. 1, 1949. There is no change in fees in connection with Part I of the examination.

Aid to Neurosurgeons in Europe.—At a meeting of the Academy of Neurological Surgery, a neurosurgeons' fund was initiated to send food and clothing to neurosurgeons in Europe. An appeal has been made to all neurologic surgeons in the United States and Canada, according to Dr. Joseph P. Evans, University of Cincinnati, secretary-treasurer of the fund. Dr. Evans recently returned after serving in Austria on a medical mission sponsored by the Unitarian Service Committee and the United Nations World Health Organization; others on the committee are: Dr. Howard C. Naffziger, San Francisco, chairman of the 1946 Unitarian Service Committee mission to Poland; Dr. Leo M. Davidoff, Brooklyn, member of the committee's 1946 mission to Czechoslovakia; Dr. A. Earl Walker, Baltimore; Dr. Franc D. Ingraham and Dr. W. Jason Mixter, Boston; Dr. Percival D. Bailey, Chicago, and Dr. Wilder G. Penfield, Canada.

Amputee Institute.—The second annual Amputee Institute will be held April 1, 8, 15, 22 and 29 at the Hasbrouck Heights Hospital in New Jersey. The institute will endeavor to correlate the efforts of the general surgeon, the orthopedic surgeon, the limb manufacturer and associated interests and promote for civilian amputees the same help as that provided by the Army and Navy for members of the armed forces who lost limbs in World War II. The institute will be under the personal direction of Dr. Henry H. Kessler, Newark, N. J., chairman of the Rehabilitation Committee of the American Medical Association Council on Industrial Health. In connection with the institute an intensive course in amputation and selection of prosthesis will be given for physicians and associated workers from 9 a.m. to 12 noon and from 2 to 5 p.m. Sponsors of the institute are reported to be the Hasbrouck Heights Hospital Association, the National Council of Rehabilitation, the New Jersey State Elks Crippled Children's Committee, Orthopedic Appliance and Limb Manufacturers Association, the New Jersey Crippled Children's Commission and the Federal Security Agency's Office of Vocational Rehabilitation. The registration fee is $10. Those planning to attend should notify the registrar, Hasbrouck Heights Hospital.

Joint Crystallographic Meeting.—The American Society for X-Ray and Electron Diffraction and the Crystallographic Society of America will hold their first joint meeting at Yale University, New Haven, Conn., April 1-3. Detailed notices have been sent to members of the two societies. Nonmembers who desire information may obtain it from Elizabeth A. Wood, secretary, American Society for X-Ray and Electron Diffraction, Bell Telephone Laboratories, Murray Hill, N. J., or William Parrish, secretary, Crystallographic Society of America, Phillips Laboratories, Inc., Irvington-on-Hudson, N. Y.

Broncho-Esophagological Association.—The twenty-ninth annual meeting of the American Broncho-Esophagological Association will be held in Atlantic City, N. J., at Chalfonte-Haddon Hall April 7-8. A resume of the program follows:

Louis H. Clerf, Philadelphia, Bronchial Adenomas.
Joseph P. Atkins, Philadelphia, Fibrocystic Disease of the Pancreas and Its Relation to Pulmonary Suppuration.
Clyde Heatly, Rochester, N. Y., Bronchoscopic Examinations in the Newborn.
Paul H. Holinger, Chicago, Tracheal and Bronchial Obstruction Due to Cardiovascular Anomalies.
Charles M. Norris, Philadelphia, Bronchospirography.
F. Johnson Putney, Philadelphia, Hiatus Hernia of the Esophagus.
Archibald R. Judd, Hamburg, Pa., Syphilitic Tumor of the Bronchus.
Chevalier L. Jackson, Philadelphia, The Present Status of Broncho-Esophagology in Latin America.
William P. Longmire, Jr., Baltimore, Reconstruction Surgery of the Trachea.
John J. O'Keefe, Philadelphia, Streptomycin Therapy in Tracheal and Bronchial Tuberculosis.
Ricardo Tapia, Mexico, D.F., Mexico, Rhinoscleroma of the Bronchus.
Francis W. Davison, Danville, Pa., Allergic Manifestations of Pulmonary Disease.
Stanton A. Friedberg, Chicago, Hemiptysis Due to Chronic Mediastinal Venous Obstruction.
Frederick T. Hill, Waterville, Maine, Granuloma of the Larynx Due to Intratracheal Anesthesia.

American Institute of Biological Sciences.—An American Institute of Boilogcal Sciences was formally established February 20 to help the various biologic societies to discharge more effectively those functions which are common concern to them all, but which they cannot adequately exercise as individual societies. As a part of the National Research Council the Institute will also provide biologists with an agency through which they can maintain close relations with governmental activities and other fields of science represented within the National Research Council. The governing board elected the following officers: chairman, Ralph E. Cleland, Ph.D., Indiana University, Bloomington-Indianapolis; vice chairman, Elmer G. Butler, Ph.D., Princeton University, Princeton, N. J.; members for three years, Wallace O. Fenn, Ph.D., Rochester, N. Y.; member for two years, Theodore C. Byerly, Ph.D., Bureau of Animal Husbandry, U. S. Department of Agriculture, Washington, D. C., and member for one year, Frank P. Cullinan, Ph.D., Bureau of Plant Industry, U. S. Department of Agriculture, Beltsville, Md. Twelve societies and the National Research Council named directors to the governing board, and twelve other societies that consider joining the Institute appointed observers.

Fellowships in Child Guidance Clinic Psychiatry.—The American Association of Psychiatric Clinics for Children is offering fellowships for training in child guidance clinic psychiatry under the auspices of the U. S. Public Health Service, the Commonwealth Fund and some local funds. The training is for positions in community clinics where psychiatrists, psychologists, social workers and others collaborate in the treatment of children with emotional or mental illness. Most of the fellowships are for two years, some for one. The stipend is $3,000 for the first year, more for the second. Prerequisites are graduation from an approved medical school, a general internship and two years of general psychiatry. Opportunity is provided for the fellow to develop his own skills in an outpatient service with the support of a carefully planned training program and adequate supervision. The training centers are selected on the basis of standards which have been established by the association, and the fellowships are awarded by a committee of this organization. For information write Dr. Abraham Z. Barhash, executive assistant, the American Association of Psychiatric Clinics for Children, 1790 Broadway, New York 19.

International Congress on Mental Health.—Grants totaling $50,000 to support the contribution of the United States to the first International Congress on Mental Health to be held in London next August were announced February 11 by Dr. Frank Fremont-Smith, chairman of the Executive Committee of the International Committee for Mental Hygiene, 1790 Broadway, sponsor of the congress. "Mental Health and World Citizenship" will be dealt with at the congress, which will be attended by an estimated two thousand psychiatrists, social workers and others from forty-four countries, including five hundred persons from the United States. According to Dr. Fremont-Smith, it is planned to form a World Federation for Mental Health as a result of the congress. Two central commissions have been set up in New York, one under the chairmanship of Lyman Bryson, LL.D., New York, to collate material on the general theme, the other under the chairmanship of Dr. David M. Levy, to report on the effect of war on children. To carry out the work of the congress additional funds are required, it was pointed out by Dr. Fremont-Smith, and plans are under way to raise an additional $200,000. Donors are the Commonwealth Fund, 41 East Fifty-Seventh Street, $20,000; the Milbank Memorial Fund, 40 Wall Street, $10,000, and the United States Public Health Service, Washington, D. C., $20,000. Previous donations totaling $35,000 have already been announced from Imperial Chemical Industries, Ltd., Unilever, Ltd. (Lever Bros.) London, and the Josiah Macy Jr. Foundation of New York City.

United Nations Crime Prevention Study.—Dr. Manfred S. Guttmacher, Baltimore, has been appointed consultant-psychiatrist to the World Health Organization Interim Commission. He will take part in a special study of the prevention of crime and the treatment of offenders undertaken by the social commission of the United Nations Economic and Social Council. The purpose of the study is to provide a plan for international action. Dr. Guttmacher's work will relate to: heredity as a factor in the causation of crime; prevention of crime; medical and psychiatric factors in the genesis of early criminal careers; medical and psychiatric methods for the treatment of juvenile and adolescent offenders, and medical and psychiatric care for the treatment of adults in confinement. During the war Dr. Guttmacher served as a lieutenant colonel in the Surgeon General's office and was awarded the Legion of Merit for his psychiatric work. He is psychiatric consultant to the Second Army and consulting psychiatrist to the Veterans Administration.

Heroin Seized in New York.—The *New York Times* reports the seizure of $150,000 worth of heroin (diacetylmorphine) smuggled from Turkey and the arrest on February 7 of two seamen for its possession. The 73,416 grains (4,757 Gm.) of the drug were carried in a cigar box. The men, who were about to board a train to Philadelphia when arrested, said they had obtained the diacetylmorphine on the Istanbul waterfront in exchange for American goods scarce in Turkey. The men, according to Col. Garland H. Williams, supervisor of the United States Bureau of Narcotics, district 2, had made frequent trips to Philadelphia since their arrival trying to sell the drug at high prices.

Dr. Cori Awarded Gibbs Medal.—Dr. Carl F. Cori, professor of biochemistry, Washington University School of Medicine, St. Louis, a 1947 Nobel Prize winner, has been designated the winner of the Willard Gibbs Medal of the Chicago section of the American Chemical Society. Dr. Cori's achievements in research on processes by which the human body converts sugar into energy won the award.

Personal.—Dr. John Rock, Brookline, Mass., and Dr. Richard N. Pierson, New York, in recognition of their service toward healthier marriage and parenthood were given the Albert and Mary Lasker Foundation Awards for 1948 at the recent annual dinner of the Planned Parenthood Federation of America in New York.

FOREIGN

Service Committee Opens Polish Hospital.—The Kosciuszko Hospital was formally opendd in Piekary Slaskie, Poland, February 22 in the presence of the of the officials of the Polish government and the United States Embassy. The hospital is the project of the Unitarian Service Committee and the Polish National Social Insurance Institution. It stands on a filled-in zinc mine in the Silesiain mining valley and is to serve the medical needs of this territory, particularly those of the miners. Traumatic surgery will be the specialized field of the hospital's activity. The Unitarian Service Committee has undertaken to supply American personnel to work with the Polish staff and to teach newest American technics. Much of the equipment has already been installed. More than 100 persons are now hospitalized, and eventually the hospital will have a capacity of three hundred to three hundred and fifty beds.

CORRECTION

Carbon Monoxide Poisoning.--In the abstract under this title in THE JOURNAL, Dec. 27, page 1182, line 14 of the second column should read: 'oxygen with 5 per cent carbon dioxide' not carbon monoxide.

Deaths

James Vance May ⊕ Belmont, Mass.; born in Lawrence, Kan., on July 6, 1873; University of Pennsylvania Department of Medicine, Philadelphia, 1897; an Affiliate Fellow of the American Medical Association; specialist certified by the American Board of Psychiatry and Neurology; lecturer on mental hygiene at the Harvard University School of Public Health from 1933 to 1936; member and past president of the New England Society of Psychiatry, Massachusetts Psychiatric Society and the American Psychiatric Association; fellow of the American Association for the Advancement of Science and the American Academy of Arts and Sciences; member of the International Committee for Mental Hygiene and the National Committee for Mental Hygiene; corresponding member of the Royal Medico-Psychological Association of Great Britain and foreign associate member of the Société Médico-Psychologique, Paris; served during the Spanish-American War and World War I; at one time assistant physician of the Binghamton (N. Y.) State Hospital, superintendent of the Matteawan State Hospital, Fishkill-on-Hudson, N. Y., Grafton (Mass.) State Hospital and the Boston State Hospital; author of "Mental Diseases"; died in the Faulkner Hospital, Boston, Dec. 24, 1947 aged 74

Harry Brooker Mills, *Philadelphia; born April 23, 1869;* Medico-Chirurgical College of Philadelphia, 1897; emeritus professor of pediatrics at the Temple University School of Medicine; formerly assistant professor of pediatrics at his alma mater; member of the American Medical Association; served as president of the staff and chairman of the medical board of Temple University Hospital; consulting pediatrist at St. Agnes' Hospital; affiliated with the Skin and Cancer Hospital, the Philadelphia Convalescent Home for Children, at Langhorne, and the Ocean City Seashore Home for Babies; member of the consulting staff of the Eastern State Penitentiary and of the courtesy staffs of the Jewsh, Germantown and Doctors' hospitals; the H Brooker Mills Pediatric Society, a Temple University organization, was founded in his honor; died in Ridley Park Dec. 30, 1947, aged 78.

Frank Chaffee Neff ⊕ Kansas City, Mo.; born in Winchester, Ind., in 1872; University Medical College of Kansas City, 1897; in 1924 joined the faculty of the University of Kansas School of Medicine in Kansas City, Kan., where he retired as professor and head of the department of pediatrics in 1945; an Affiliate Fellow of the American Medical Association, serving as secretary of the Section on Diseases of Children, 1912-1913, and chairman, 1920-1921 specialist certified by the American Board of Pediatrics, Inc.; member of the American Pediatric Society and the American Academy of Pediatrics; past president of the Central States Pediatric Society; affiliated with the Children's Mercy and Kansas City General hospitals; died in the University of Kansas Hospital, Kansas City, Kan., Dec. 3, 1947, aged 75.

Nathan Osher Ratnoff ⊕ *New York; born in 1875;* Baltimore University School of Medicine, 1899; president of the American Jewish Physicians' Committee, which he organized in 1921 to build and maintain a medical school and university hospital as a part of the Hebrew University in Palestine, where he was a governor; this work resulted in the establishment of the Nathan Ratnoff Medical School of the Hebrew University; for many years a trustee of the Foundation of Jewish Maternity Hospital, where he served as attending obstetrician, medical director and secretary to the board of directors; consultant director and from 1930 until his retirement in 1945 medical director of Beth Israel Hospital; died Dec. 23, 1947, aged 72, of coronary sclerosis.

Noel Catching Womack ⊕ Jackson, Miss.; born 1879; Jefferson Medical College of Philadelphia, 1905; specialist *certified by* the American Board of Pediatrics; member of the American Academy of Pediatrics; fellow of the American College of Physicians; one of the organizers and first president of the Mississippi State Pediatric Society; consulting pediatrician to the Mississippi State Tuberculosis Sanatorium and the Mississippi State Charity Hospital; chief of the pediatric department of the Jackson Infirmary; died Dec. 26, 1947, aged 68, of coronary sclerosis.

Frank Peabody Atkinson ⊕ Columbus, Ohio; Ohio Medical University, Columbus, 1903; served during the Spanish-American War and World War I; died in the Grant Hospital Dec. 26, 1947, aged 70.

Benjamin Spafford Barnes ⊕ Shenandoah, Iowa; Rush Medical College, Chicago, 1909; past president of the Page County Medical Society; served during World War I; affiliated with the Hand Memorial Hospital, where he died Dec. 13, 1947, aged 63, of coronary occlusion.

Paul Hogue Beard, *Indianapolis; Northwestern University* Medical School, Chicago, 1927; member of the American Medical Association; fellow of the American College of Surgeons; served during World War II; affiliated with Methodist and St. Vincent's hospitals; died *Dec. 22, 1947,* aged 45.

Edward Bollinger, Columbia, Ill.; Illinois Medical College, Chicago, 1900; member of the American Medical Association; formerly affiliated with the state hospitals in Kankakee, Anna and Alton; died in the Christian Welfare Hospital in East St. Louis, Dec. 15, 1947, aged 71, of cerebral hemorrhage.

John Edson Bowers, Brandywine, Md.; George Washington University School of Medicine, Washington, D. C., 1908; died in the Providence Hospital, Washington, D. C., Dec. 16, 1947, aged 69.

Harry Edward Braner ⊕ Hamburg, N. Y.; University of Buffalo School of Medicine, 1905; examining physician for the draft board during World Wars I and II; affiliated with the Millard Fillmore Hospital in Buffalo and Our Lady of Victory Hospital in Lackawanna; died Dec. 2, 1947, aged 64, of coronary disease.

John Joseph Brennan ⊕ Scranton, Pa.; Medico-Chirurgical College of Philadelphia, 1898; past president of the Lakawanna County Medical Society; superintendent of the Westside Hospital, where he died Dec. 8, 1947, aged 73.

Luke D. Broughton, Brooklyn; Eclectic Medical College of the City of New York, 1881; New York Homeopathic Medical College, 1882; died Dec. 5, 1947, aged 88, of senility.

Thomas Earl Burgess, Toledo, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; formerly member of the city health department; died in Mercy Hospital Dec. 15, 1947, aged 81, of myocardial failure.

John Robert Burns, Penns Grove, N. J.; Bennett Medical College, Chicago, 1913; physician for du Pont de Nemours & Company; died Dec. 1, 1947, aged 59, of carcinoma of the esophagus.

Elizabeth M. Cahill, Chicago; Chicago College of Medicine *and Surgery, 1909; died in December 1947, aged 72.*

Paul Wiles Carmichael, Trinidad, Colo.; University of Colorado School of Medicine, Denver, 1915; member of the American Medical Association; affiliated with the Mount San Rafael Hospital; died in the Corwin Hospital, Pueblo, Dec. 21, 1947, aged 59, of carcinoma.

Willis H. Carr, Cynthiana, Ky.; Medical College of Ohio, Cincinnati, 1887; died Dec. 18, 1947, aged 84, of coronary occlusion.

John Blayney Claypool, Niles, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1893; died in a hospital at Youngstown Dec. 5, 1947, aged 78, of intestinal obstruction.

Emmanuel Robert Clemons, Chicago; Meharry Medical College, Nashville, Tenn., 1916; affiliated with Provident Hospital; died Dec. 5, 1947, aged 56, of coronary thrombosis.

George Vincent Coleman, Providence, R. I.; Harvard Medical Schol, Boston, 1919; member of the American Medical Association; chief surgeon for the Providence police and fire Departments; affiliated with St. Joseph Hospital and Providence Lying-In hospitals; died Dec. 10, 1947, aged 56, of pneumonia and myocarditis.

Frederic Charles Conway ⊕ Albany, N. Y.; Albany *Medical College, 1906;* associate professor of medicine at his alma mater; fellow of the American College of Physicians; member of the board of education and of the examining board of the state retirement system; member of the House of Delegates of the American Medical Association in 1939 and 1940; affiliated with St. Peter's Hospital; died Dec. 6, 1947, aged 65, of coronary thrombosis.

Elmer Humphrey Copeland, Northampton, Mass.; New York Homeopathic Medical College and Hospital, New York, 1893; member of the American Medical Association; affiliated with the Cooley Dickinson Hospital; vice president of the Nonotuck Savings Bank; died Dec. 25, 1947, aged 86, of heart disease.

Chester Owen Cramer ⊕ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1932; served during World War II; member of the city board of health; affiliated with Mount Carmel Hospital; died Dec. 11, 1947, aged 43, of coronary thrombosis.

Ralph Cline Cross ⊕ Texarkana, Texas; University of Tennessee College of Medicine, Memphis, 1925; formerly secretary of the Bowie County Medical Society; served during World War I and on the Selective Service Board during World War II; died in the Michael Meagher Memorial Hospital, Texarkana, Ark., Dec. 15, 1947, aged 47, of heart disease.

Charles Leverett Curtis ⊕ Salem, Mass.; Medical School of Maine, Portland, 1909; fellow of the American College of Surgeons; member of the New England Surgical Society; affiliated with the Danvers (Mass.) State Hospital, Cable Hospital, Ipswich, North Shore Babies Hospital and the Salem Hospital, where he died Dec. 11, 1947, aged 62.

Charles Payson Deyoe, Pasadena, Calif.; University of Maryland School of Medicine, Baltimore, 1883; died Dec. 16, 1947, aged 87.

Hervey John Smith Dickson, Springfield, Ohio; Medical College of Ohio, Cincinnati, 1891; formerly health commissioner of Champaign County; died Nov. 17, 1947, aged 86.

Lucius Boardman Donkle ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; served as assistant clinical professor of surgery at the Loyola University School of Medicine on the staff of St. Bernard's Hospital; died January 7, aged 70, of carcinoma of the esophagus.

Wilbert G. Drinkwater ⊕ Gormania, W. Va.; Eclectic Medical Institute, Cincinnati, 1888; honorary life member of the West Virginia State Medical Association; died in the Uniontown (Pa.) Hospital Dec. 20, 1947, aged 87, of benign prostatic hypertrophy with uremia.

Gregory Joseph Egan ⊕ La Crosse, Wis.; Rush Medical College, Chicago, 1901; on the staff of St. Francis Hospital; died Dec. 6, 1947, aged 70, of intestinal carcinoma and bronchopneumonia.

Albert Mortem Elton ⊕ Newport, Ark.; University of Arkansas School of Medicine, Little Rock, 1906; fellow of the American College of Surgeons; past president of the Jackson County Medical Society; served during World War I; formerly affiliated with the U. S. Public Health Service; member of the board of trustees of the Arkansas State Teachers College at Conway; chairman of the board of directors of the First National Bank; died in a local hospital Dec. 17, 1947, aged 65.

Edward Harris Fischer ⊕ Louisville, Ky.; University of Louisville School of Medicine, 1917; served during World War I; died in St. Joseph Infirmary Dec. 19, 1947, aged 53.

Herbert Maurice Flemming ⊕ Ambridge, Pa.; University of Pittsburgh School of Medicine, 1927; affiliated with the Beaver Valley General Hospital in New Brighton and the Rochester (Pa.) General Hospital; died Dec. 2, 1947, aged 47, of injuries received when his automobile was struck by a truck near Aliquippa.

T. H. Fowler, Nobility, Texas (licensed in Texas under the Act of 1907; died Nov. 30, 1947, aged 73, of chronic myocarditis.

Arthur Sheldon Grant ⊕ New Britain, Conn.; University and Bellevue Hospital Medical College, New York, 1908; fellow of the Radiological Society of North America; served during World War I; for many years affiliated with the New Britain General Hospital; died Dec. 11, 1947, aged 67, of acute coronary occlusion.

Arthur Moses Greenwood ⊕ Boston; Harvard Medical School, Boston, 1902; specialist certified by the American Board of Dermatology and Syphilology; member of the American Dermatological Association, American Academy of Dermatology and Syphilology and the New England Dermatological Society; served on the staffs of the Massachusetts General, New England Deaconess and Palmer Memorial hospitals; died in Laconia, N. H., Dec. 14, 1947, aged 71, of cerebral hemorrhage.

Nettie Hammond, Hermosa Beach, Calif.; University of Southern California College of Medicine, Los Angeles, 1896; died Dec. 1, 1947, aged 78.

Hal White Hardin, Dallas, Texas; Baylor University College of Medicine, Dallas, 1939; member of the American Medical Association; served during World War II; on the staffs of the Baylor, Children's and Veterans Administration hospitals; died Dec. 29, 1947, aged 32, of carcinoma of the colon and liver.

Timothy Louis Harrington, Milwaukee; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the American Medical Association; formerly medical director of the River Pines Sanatorium in Stevens Point, Wis.; for many years a member of the staff of the Wisconsin Anti-Tuberculosis Association; died Dec. 13, 1947, aged 81, of coronary heart disease.

Abel Le Compte Hill, Kings Mountain, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1930; member of the American Medical Association; a captain in the medical corps, Army of the United States, with the 82d airborne division during World War II; died suddenly Dec. 19, 1947, aged 40.

Myrtle Mary Ozias Hill, Kansas City, Mo.; Barnes Medical College, St. Louis, 1909; for many years on the staff of St. Joseph Hospital, where she died Dec. 19, 1947, aged 61, of uremia secondary to carcinoma.

George Franklin Holitik, Waldron, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1923; died Dec. 15, 1947, aged 48

Joseph P. Holt Sr., Versailles, Ky.; Louisville (Ky.) Medical College, 1904; affiliated with Woodford Memorial Hospital; died Dec. 19, 1947, aged 64, of coronary occlusion.

Samuel Rice Hopkins, Dearborn, Mich.; Rush Medical College, Chicago, 1900; fellow of the American College of Surgeons; formerly professor of surgical pathology at Creighton University School of Medicine in Omaha; an officer during World War I; medical advisor for the Detroit Reginoal Office of the Disabled American Veterans and the American Legion; for many years affiliated with the Veterans Administration Hospital, where he died Dec. 19, 1947, aged 71, of cerebral hemorrhage and hypertension.

John Freeman Humphrey, Saratoga Springs, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1891; member of the American Medical Association; served as a member and president of the board of education; for many years affiliated with the Saratoga Hospital, where he died Dec. 5, 1947, aged 82.

Douglas Algot Jackson, Kansas City, Mo.; University of Louisville (Ky.) School of Medicine, 1934; member of the American Medical Association; an officer in the medical corps, Army of the United States, during World War II; affiliated with the Research, St. Joseph and Trinity Lutheran hospitals; died Dec. 7, 1947, aged 39, of heart disease.

Rilus Eastman Jones, Los Angeles; Medical College of Indiana, Indianapolis, 1901; died Dec. 8, 1947, aged 69.

Edward Payson Judd, Cleveland; Western Reserve University Medical Department, Cleveland, 1931; affiliated with the Lakeside Hospital, where he died Dec. 31, 1947, aged 42, of pneumonia.

Elizabeth Abbie Keay, Mars Hill, Maine; Woman's Medical College of Baltimore, 1910; died Dec. 14, 1947, aged 73.

Frank John Kiefer, Louisville, Ky.; Hospital College of Medicine, Louisville, 1898; member of the American Medical Association; died Dec. 16, 1947, aged 84.

George Clifford King ⊕ Fall River, Mass.; Tufts College Medical School, Boston, 1909; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics and the New England Pediatric Society; formerly member of the board of health; affiliated with Truesdale Hospital; died Dec. 21, 1947, aged 61, of coronary thrombosis.

John Bartlett Kistler, Newcomerstown, Ohio; Eclectic Medical College, Cincinnati, 1924; member of the American Medical Association; formerly medical inspector in the division of communicable diseases of the state department of health; died Dec. 22, 1947, aged 51, of heart disease.

Jacob Kramer, Los Angeles; Long Island College Hospital, Brooklyn, 1907; died in December 1947, aged 62.

Frederick Milton Kueffer, San Carlos, Calif.; Homeopathic Medical College of Missouri, St. Louis, 1905; died in December 1947, aged 71.

Stanley Joseph Lassaline, Detroit; Detroit College of Medicine and Surgery, 1915; member of the American Medical Association; died Dec. 5, 1947, aged 54, of coronary thrombosis.

William John Lord, Great Barrington, Mass.; Albany (N. Y.) Medical College, 1939; interned at St. Peter's Hospital in Albany, N. Y., and St. Joseph's Hospital in Toronto, Canada; served during World War II; diplomate of the National Board of Medical Examiners; died Dec. 16, 1947, aged 40, of a possible fracture of skull and gastric hemorrhage.

Forest Ray Mildren ⊕ Las Vegas, Nev.; Chicago College of Medicine and Surgery, 1916; served in the medical corps of the U. S. Army in France during World War I; died Dec. 14, 1947, aged 57, of coronary thrombosis.

Frederick Christopher Miller, Prospect, Ky.; Lousvlle (Ky.) Medcal College, 1890; died Dec. 25, 1947, aged 79.

Hugo Miller, Kinmundy, Ill.; Beaumont Hospital Medical College, St. Louis, 1895; member of the American Medical Association; died in the Salem (Ill.) Memorial Hospital Dec. 14, 1947, aged 83, of pneumonia.

Samuel Rush Miller ⊕ Knoxville, Tenn.; born in Bedford County, Tenn., July 7, 1869; Vanderbilt Universty School of Medicine, Nashville, 1893; member of the House of Delegates of the American Medical Association in 1911, 1912 and 1916; fellow of the American College of Surgeons; district surgeon for the Louisville and Nashville Railroad; surgeon for the Southern Railway; consulting surgeon for the Knoxville General Hospital; visting surgeon for St. Mary's Memorial Hospital and the Fort Sanders Hospital, where he died Dec. 24, 1947, aged 78, of Parkinson's disease.

Harry Fitzroy Mitchell ⊕ South Bend, Ind.; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1889; affiliated wth the Memorial Hospital, where he died Dec. 21, 1947, aged 81, of carcinoma of the prostate and pneumonia.

Edwin Jay Moffit, Los Angeles; Drake University Medical Department, Des Moines, 1896; member of the American Medical Association; affiliated with the Presbyterian Hospital, Olmstead Memorial, where he died Dec. 20, 1947, aged 75, of lymphatc leukema and coronary occlusion.

Caldwell Morrison, South Orange, N. J.; New York Homeopathic Medical College and Hospital, New York, 1889; member of the Newark Induction Board during World Wars I and II; affiliated with the East Orange (N. J.) General Hospital; died in the Fair Oaks Sanatorium in Summit Dec. 24, 1947, aged 81, of coronary sclerosis.

Charles Henry Muschlitz ⊕ Slatington, Pa.; Jefferson Medical College of Philadelphia, 1904; fellow of the American College of Surgeons; member of the school board; director of the Slatington Citizens National Bank; affiliated with the Allentown (Pa.) Hospital; died Dec. 3, 1947, aged 66, of ruptured abdominal aneurysm.

Edwin Dunn Newman, Brooklyn; Long Island College Hospital, Brooklyn, 1896; died Dec. 20, 1947, aged 73, of cerebral hemorrhage.

John C. Nunn, Quincy, Ill.; Hospital College of Medicine, Louisville, 1896; died Dec. 24, 1947, aged 75, of a malignant tumor of the right parotid gland.

Howard Holland Nye ⊕ Paterson, N. J.; Jefferson Medical College, 1921; past president of the Passaic County Medical Society; affiliated with the Paterson General Hospital; died Dec. 28, 1947, aged 57, of coronary thrombosis.

Ewing Lamb Palmore, Glasgow, Ky.; Hospital College of Medicine, Louisville, 1905; member of the American Medical Association; past president of the Barren County Medical Society; affiliated with the T. J. Samson Community Hospital, where he died Dec. 25, 1947, aged 68, of cerebral hemorrhage.

Ralph Emory Peck, Cordelia, Calif.; Cooper Medical College, San Francisco, 1898; died Dec. 18, 1947, aged 76.

George Allen Perkins ⊕ Washington, Pa.; University of Cincinnati College of Medicine, 1916; past president of the Washington County Medical Society; affiliated with Washington Hospital; died Dec. 19, 1947, aged 62.

John Howard Rahter ⊕ Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; died in Harrisburg Hospital Dec. 17, 1947, aged 63, of coronary thrombosis.

Augustus Baxter Riley, Hartford, Ky.; Louisville Medical Colege, 1906; served during Word War I; died Dec. 19, 1947, aged 71, of heart disease.

Lambert William Rosenbaum, Chicago; Jenner Medical College, Chicago, 1913; member of the American Medical Association; died Dec. 29, 1947, aged 64, of carcinoma of the liver.

John Phillip Saling, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1899; member of the American Medical Association; affiliated with St. Joseph's Hospital; died Dec. 24, 1947, aged 73, of cerebral arteriosclerosis.

Thomas Nelson Sample, Fresno, Calif.; Cooper Medical College, San Francisco, 1901; member of the American Medical Association; died Dec. 23, 1947, aged 70, of uremia.

Carl Eric Sandberg, Chicago; Chicago College of Medicine and Surgery, 1908; served on the staff of the Englewood Hospital, where he died January 8, aged 78, of cerebral hemorrhage.

William David Sansum ⊕ Santa Barbara, Calif.; Rush Medical College, Chicago, 1915; formerly practiced in Chicago, where he was an associate in medicine at Rush Medical College; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the National Gastroenterological Association; affiliated with the Santa Barbara Cottage Hospital; died January 5, aged 67, of pontine hemorrhage.

Frank George Scammell, Trenton, N. J.; Medico-Chirurgical College of Philadelphia, 1899; member of the American Medical Association; fellow of the American College of Surgeons; past president of the Medical Society of New Jersey and of the Mercer County Medical Society; surgeon to the Mercer Hospital; consulting surgeon, Orthopedic Hospital, Trenton, and the New Jersey State Hospital, Greystone Park, died Dec. 6, 1947, aged 70, of carcinoma of the prostate.

John Francis Schefcik, Los Angeles; Minneapolis College of Physicians and Surgeons, 1900; also a graduate in pharmacy; died Dec. 23, 1947, aged 75.

Philipp Schonwald ⊕ Seattle; Medizinische Fakultät der Universität, Wien, Austria, 1905; fellow of the American College of Chest Physicians and of the American College of Physicians; died Dec. 20, 1947, aged 67.

Elias Selinger ⊕ Chicago; Northwestern University Medical School, Chicago, 1924; professor of ophthalmology at the Cook County Graduate School; at one time on the faculty of Rush Medical College; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Michael Reese, Cook County and Mount Sinai hospitals; died in El Paso, Texas, Dec. 21, 1947, aged 49, of coronary occlusion.

Jesse Washington Shaw, St. Louis; St. Louis College of Physicians and Surgeons, 1908; found dead Dec. 2, 1947, aged 63, of ruptured left ventricle.

Edwin Heddon Shepard ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1905; served on the faculty of his alma mater; chief examiner for the Syracuse branch of the Travelers Insurance Company; past president of the Syracuse Academy of Medicine; formerly on the staff of the Crouse-Irving Hospital, where he died Dec. 26, 1947, aged 69, of acute myocardial infarction, coronary sclerosis and diabetes mellitus.

William Palmer Sherman, Aurora, Ill.; Rush Medical College, Chicago, 1889; fellow of the American College of Surgeons; affiliated with St. Joseph Mercy Hospital, where he died Dec. 10, 1947, aged 84, of hypostatic congestion of the lungs.

William Arthur Shields, Sacramento, N. Mex.; University of Texas School of Medicine, Galveston, 1902; died in the Municipal Hospital in Artesia recently, aged 69, of coronary occlusion.

John M. Shirley, St. Marys, Mo.; St. Louis College of Physicians and Surgeons, 1890; also a graduate in pharmacy; died Dec. 9, 1947, aged 89, of bronchopneumonia.

Robert William Siddle, Powell, Wyo.; Rush Medical College, Chicago, 1934; died recently, aged 45, of heart disease.

Ferdinand Francis Siegel, Brooklyn; Long Island College Hospital, Brooklyn, 1916; member of the American Medical Associaton; served during World War I; formerly supervising medical inspector for the board of health; died in the Bushwick Hospital Dec. 5, 1947, aged 56, of chronic nephritis and hypertension.

Cash L. Simmons, Long Beach, Calif.; Ensworth Medical College, St. Joseph, 1892; died Dec. 26, 1947, aged 81.

Richard M. Skinner, Flemingsburg, Ky.; Homeopathic Hospital College, Cleveland, 1886; died in Ironton, Ohio, Dec. 20, 1947, aged 85.

Archibald Smith, Atlanta, Ga.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the American Medical Association; formerly on the faculty of the Atlanta School of Medicine; served during World War I; affiliated with the Grady and Crawford W. Long hosptals; died Dec. 20, 1947, aged 73, of cerebral hemorrhage.

Seth Paine Smith ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1905; formerly on the faculty of Barnes Medical College; member of the staff of the De Paul Hospital; died in December 1947, aged 65, of coronary sclerosis.

Frank Wallace Smith, York Village, Maine; Dartmouth Medical School, Hanover, N. H., 1883; died Dec. 11, 1947, aged 88.

Andrew Jackson Stufflebam, Humansville, Mo.; St. Louis College of Physicians and Surgeons, 1898; member of the American Medical Association; past president of the Dallas-Hickory-Polk Counties Medical Society; served as secretary of the city board of health; died recently, aged 75.

Henry Fletcher Tatum, Meridian, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1897; served on the staff of the East Mississippi State Hospital; died Dec. 11, 1947, aged 76.

Clinton Michael Young, Kittanning, Pa.; Baltimore Medical College, 1906; died Dec. 3, 1947, aged 68.

New Method for Relief of Pain in Intractable Pelvic Cancer

From the Postgraduate Medical School Dr. Maeve Kenny has described in the *British Medical Journal* a method of caudal anesthesia which she has found successful for the relief of pain in cancer of the pelvic organs intractable to surgery. The method has the great advantage that it can be carried out by the general practitioner. The subjects of pelvic cancer may die hard, often in the prime of life and capable of service and happiness if relief of pain can be given in their remaining years without impairing their mental and bodily functions. Opium in increasing doses, neurectomies and intrathecal injection of alcohol increase the nursing responsibilities and make the last days odious to the sufferer and friends.

Caudal anesthesia is produced as follows: After anesthetizing the caudal opening of the sacral canal and the tissues down to the tough fibrous membrane closing the sacral canal by the injection of procaine solution, a 3 inch (7.62 cm.) needle is pushed through the membrane for a distance of 1 inch (2.54 cm.). The needle is attached to a syringe containing the solution of procaine, which is injected boldly. The syringe in then replaced by a 10 cc. one charged with warmed "protocaine" (procaine with butyl aminobenzoate and benzyl alcohol in arachis oil). This is injected steadily to an amount varying with the skeletal size of the patient, usually 40 to 60 cc. in about ten minutes, meanwhile testing the levels of cutaneous anesthesia to pinprick of the perineum, thighs, buttocks and abdominal wall, and asking the patient when the pain is relieved. When this is known, or if the level of the anesthesia rises to the nipple level, the injection is discontinued.

Sometimes complete relief is obtained at once, but sometimes only when the patient is eased from the left side on which she has been lying onto the right side, is made to stand up, or to lie on the back with the foot of the bed raised. A dramatic case was that of an old dancer brought to the clinic in a wheelchair with her thighs drawn up in painful spasm due to cancerous infiltration of the psoas muscles. After caudal anesthesia she straightened herself and smilingly assumed poses of the ballet, to the delight of the students. She died of cardiac metastases from cancer of the cervix. Seventeen patients with cancer of the uterus, prostate or vagina were treated. All obtained relief except those who had secondary neoplasms beyond the reach of the injections. No urinary or fecal incontinence followed use of this method, which is within the competence of the ordinary practitioner and which enables those with pelvic cancer to end their days in comparative comfort.

British Lecturers Abroad

Illustrations of the fact that one result of the war was the passage to England of the hegemony in European medicine which was claimed for Germany have been given in previous letters to The Journal. The latest manifestation is the despatch by the British Medical Association of lecturers to various European countries. A year age the council set aside the sum of $4,000 to provide lectures by distinguished practitioners to the medical profession in Europe, especially in countries occupied by the enemy during the war. Lectures on clinical pathology have been delivered in Czechoslovakia by Dr. S. C. Dyke; in Denmark on plastic surgery by Professor T. P. Kilner; in Norway on orthopedics by Mr. L. Lawson Dick, and in Spain and the Netherlands on chest surgery by Mr. C. Price Thomas. At the end of February Mr. N. R. Barrett is to visit Denmark to lecture on recent advances in chest surgery.

On returning from Norway Mr. Lawson Dick reported that medicine there bears marks of the long isolation which the country suffered. In particular the treatment of fractures shows much more of the influence of Böhler than is seen in Britain. Nearly all the doctors he met had been in concentration camps for varying periods.

ITALY

(From Our Regular Correspondent)

Jan. 15, 1948.

Italian Urologic Society

At the Twentieth National Congress of the Italian Urologic Society in Rome Professor M. Sorrentino, from the University in Naples presented a report on urinary incontinence. He discussed the various forms of incontinence: essential; that of nervous origin; regurgitation; enuresis of women. He described various methods of treatment with special consideration of the treatment that he recommends, which consists in irradiation of the bladder by short waves and the surgical treatment of enuresis in women.

Ascoli (Milan) called attention to the importance of the integration of psychic and psychopedagogic factors in the other methods of treatment of infantile enuresis. Bonino (Turin) after describing two signs, a cystoscopic and roentgenographic one, which he had observed, expressed his opinion that the method of choice may be surgical, consisting in the reconstruction of the neck of the bladder by the vaginal route in women and by the transvesical route in men.

Caporeale (Turin) discussed the surgical treatment of urinary incontinence by recalling Rochet's intervention (section of the hypogastric nerve) in cases refractory to medical and surgical treatment. The speaker made a therapeutic experiment by means of infiltration of the hypogastric ganglion with an anesthetic or alcohol in order to obtain an interruption of the peripheral nervous vesical system; on the base of the results obtained (2 cures, 3 therapeutic failures) he stated that this method should be given therapeutic trial in cases refractory to other methods of treatment.

Therapy of Cancer of the Prostate

Professor Musiani of Bologna presented a review of synthetic estrus-producing substances which may be employed for treatment of cancer of the prostate. He compared the results obtained with castration and those obtained with the administration of estrus-producing compounds. He concluded that the results obtained with the estrogenic treatment may be considered satisfactory, because in 51 per cent of the cases an immediate success was obtained with regard either to the tumor or to the metastases.

Professor Mingazzini reported on the diagnosis of cancer of the prostate. Based on his own statistics, those of others and studies of 1,700 patients, 188 of whom had cancer, he examined the incidence of cancer and the relation of cancer to hypertrophy; he insisted on the importance (1) of the data furnished by the objective examination and (2) particularly of the changes in the prostate (with regard to form, surface and consistency) and of pain. The roentgenologic, the cystoscopic and the ureteroscopic observations are likewise of great importance. With regard to surgery he discussed the limits of operability, the technic, methods of indirect surgical treatment (ligature of the vasa deferentia, castration, orchiectomy); radium and roentgen therapy, and surgical treatment combined with administration of stilbene.

Many others participated in the discussion of this subject. Bravetta of Milan treated 60 patients with cancer of the prostate with estrus-producing compounds for two and one-half years and obtained definite improvement in nearly all of them; he administered 5 mg. of the compound daily by the hypodermic route and continued this treatment for an indefinite time.

Berti Riboli of Genoa obtained encouraging results in 50 patients treated in several hospitals. Bonino of Turin obtained favorable results when castration was combined with the administration of estrus-producing compounds. Bruni of Naples obtained more favorable results in 20 patients with castration than with hormone therapy. Oberholtzer of Rome discussed the mechanism of action of the treatment of cancer of the prostate with stilbene; he concluded that at present it does not seem possible to confirm whether the drug acts as a hormone or as a chemical agent.

Establishment of a Blood Bank

The first Italian Blood and Plasma Bank has been organized in Turin following the scheme of those established in the United States. The bank will not be a substitute for the present Association of Voluntary Blood Donors but will partly support this association with the intention to perfect the blood transfusions and to make them more practical. The bank will put the products at the disposal of the physicians as follows: (*a*) whole blood, collected in a special citrated, anticoagulant solution; (*b*) human plasma, frozen or dried, and (*c*) modified globin, obtained from erythrocytes which have not been utilized during the preparation of plasma.

The classification of the blood will be warranted by the determination of the various blood groups and of the Rh factor.

Consulting Office on Genetics

The first Italian Consulting Office on Genetics has been established at the center for studies of human genetics of the University of Milan. The purpose of the consulting office is to assist physicians in evaluating data of the family history of patients with diagnostic, prognostic and therapeutic problems which sometimes can be solved only with the help of genetics. The consulting office will also give advice with regard to marriage. Counselors will be the director of the center for studies of human genetics at the university and specialists in the various branches of medicine as assistant physicians. The function of the consulting office will be purely consultative, with the exclusion of any diagnostic or therapeutic activity.

BUENOS AIRES

(From Our Regular Correspondent) Dec. 22, 1947.

The New Law for Argentine Universities

The government has proclaimed a new law for the universities, effective Jan. 1, 1948. For several months it had been projected and several times discussed in parliament and the daily press. According to the definition given, the universities are institutions for advanced teaching, the development of young students, the advancement of science and the development of the liberal professions. Their technical, teaching and scientific autonomy is guaranteed. Neither professors nor students are allowed to act directly or indirectly in politics or to intervene in situations which are foreign to their specific function.

An important change, in comparison with former rules, is that the rector of the university will not be designated by the government (executive power); he remains three years in charge. There is also a vice rector and a university council composed of the deans and vice deans of the different faculties. The rector must possess the highest title of the corresponding national faculty or be a titular professor or associate professor. His post is incompatible with any other public activity, except teaching in the same university, lecturing, research work and similar occupations. He receives 4,000 pesos per month. The vice rector substitutes for the rector if necessary or can be delegated by him for certain functions. He receives 500 pesos a month.

The university council has many functions: for instance, superior jurisdiction, control of the faculties and rules, creation of new faculties or institutes and the approval of candidates for a chair.

The faculties are led by a directing council composed of the dean and ten councilors elected by secret vote of the professors among themselves, viz. seven titular councilors (six plus the dean) and four associates. Another important change is that the dean of the faculty is not elected by the professors of the faculty (and the students) among themselves, but from a list of three names which the rector presents to the directing council of the faculty. He must be professor of the same faculty. He remains in charge for three years, and so do the ten councilors, who cannot be reelected for the following three year period. The councilors cannot occupy paid positions which are independent of the university. They cannot be designated during their mandate and for two years after their mandate has ended, for chairs, etc., created during their mandate. The dean receives 1,000 pesos a month for expenses of representation.

The professors are classified as titulars (those who occupy a chair), associates, extraordinary and honorary professors. The titular and associate professors are selected by competitive test between several candidates; with respect to the titulars a list of three names is submitted by the university to the executive who makes the designation. The associate professors must be approved by the university council. Also, persons who have not taught before can be elected if their scientific personality and work are approved; in such cases also the competitive test can be set aside under certain conditions. After four years of activity, associate professors must be confirmed as such by the university council. Every year one or two associate professors are designated as assistants of the titular professor. The extraordinary professor is designated according to his recognized reputation in his specialty, with special contract in each instance for a determinated period. He can also be of foreign nationality (the titular and associate professors may not). The retiring professor can be nominated honorary professor in recognition of his merits. The titular professors have a monthly remuneration of 1,800 pesos, which is increased 10 per cent every five years, and, if they are on a full time basis, of 3,500 pesos, which is increased 10 per cent every ten years. The associates receive 800 pesos per month if they are assistants, or 1,500 if full time.

The candidate for a university professorship begins with a period of adscription during which he has to do scientific work and teach under the direction of the titular. He takes a final examination. The next step is called complementary teaching, after which he will be authorized as lecturer, either by examination or by general competition. Everybody who has finished his university studies in a normal way and who follows his profession ten or more years and presents enough scientific work, papers, titles and the like, has the right to apply for permission to teach. If accepted, he receives the "venia docendi," i. e., permission to teach in regular and systematic form.

Every faculty has a so-called general "claustro" which includes all the titulars of the faculty plus one third as many associates, chosen by lot. Attendance at the meetings of the claustro is compulsory. It deals only with the annual report of the dean and the curriculum and plan of studies.

The student body is divided in regular and free students. Regular students must assist with the practical courses according to special prescriptions of each faculty (nothing is said about their compulsory assistance at theoretic lectures; this item had been foreseen in the original draft but had been suppressed by the senate of the parliament).

The students of each faculty elect, by lot, one representative for the directing council from among the ten best senior students. This delegate can express freely the opinion of the students he represents, but he has no vote in the decisions taken by the council.

A special organization for distributing fellowships among the regular students has been created (the "free" students cannot obtain them). There are two classes of fellowships, one for studying and one for stimulating. The first are for students of poor families; these fellows receive not only free tuition, books and so forth, but also financial aid.

To finance the expense of this new law there are two sources: the national budget and a new special tax of 2 per cent, which every employer has to pay on every salary or wages paid in Argentina, except those of domestic servants and payments made by the national, provincial and municipal authorities.

To coordinate the work of the universities and to advise the national government, a National University Council is created, comprising the rectors of all Argentine universities and presided over by the Minister for Justice and Public Instruction.

One item of the law has not yet been promulgated by the president of the republic, namely, that which determines the incompatibility of the function of a titular professor with other public activities. This has been done owing to the protest of a number of persons interested in this point, who explained the difficulties which this rule may create.

Brief Items

The First Argentine Congress of Bronchoesophagology was held, under the honorary chairmanship of Professor Chevalier L. Jackson of Philadelphia, who gave courses in Buenos Aires and in Córdoba at the invitation of the corresponding Argentine societies. Argentine chairman of the meeting was Dr. Alvaro Bence. The subjects treated were: diagnostic and therapeutic indications of bronchology and esophagology, hospital services of oral endoscopy and oral endoscopy in children.

Institute for Scientific Investigation

Last November in Buenos Aires the Institute for Biochemical Investigations (Foundation Campomar) was inaugurated. The institute was donated and is maintained by Mr. Jaime Campomar. It is a sister institute to that of Dr. B. A. Houssay, situated beside it and in interdependence with it. Its director, Dr. Luis F Leloir, is a pupil of Houssay, and so are also the collaborators of the new institute. It consists of four laboratories which are specially equipped for metabolic research and enzyme studies.

Orthopedic Traction on the Skeleton

Dr. Carlos E. Ottolenghi, associate professor of orthopedic surgery, Faculty of Medicine of Buenos Aires, has completed an investigation for which he has just received the prize which is annually awarded by the Argentine Society of Surgeons. Ottolenghi studied in dogs and rabbits, as well as clinically, the tolerance of the organism for iron wire and traction, particularly the reactions of the tissues, the histopathologic changes, the technic of application and the resistance of different kinds which the wire has to overcome, the direction of the traction powers and the application of wire in children. Infection and exaggerated traction are the most important dangers of traction on the skeleton. He prefers to put the wires in tension according to Kirschner's technic without using the nails of Steinmann.

TURKEY

(From Our Regular Correspondent)

Ankara, Jan. 30, 1948.

Saliva Stones

A colonel at the military academy, Gülhane Hospital, Professor Dr. Necdet Albay encountered 3 cases of saliva stones and has published his observations. The first case was in a young man aged 22, who twenty days prior to admission to the hospital noticed in the lower jaw a swelling the size of a walnut. During meals the swelling and the pain increased and extended to the root of the tongue. As the roentgen examination did not show the stone, it was decided to excise the gland, which was done with the patient under local anesthesia. There was a small purulent pocket beneath the lower lobe and surrounded by extensive infiltration. Embedded in the gland was a stone the size of a pea. The gland was removed; the patient recovered and was discharged after fifteen days.

The second case concerned a woman, aged 36, who for three weeks had felt a swelling accompanied by pain in the lower jaw on the right side. One week prior to admission hospital the pain increased and there was swelling toward the tongue. The pain became unbearable. On roentgen examination the shadow of a small stone was visible. With the patient under local anesthesia the excision was performed, releasing an abundance of pus. After ten days' treatment the patient was discharged as cured.

The third case occurred in a man aged 45, under whose tongue there was a suppurative process from which, from time to time, small stones were cast out, under the lower jaw on the left side. A swelling which became especially painful during meals had developed three months' previously. The patient, who was advised to stay at the hospital, promised to return the next day but failed to do so.

Of the two stones excised, 1 weighed 5 Gm., the other 8 Gm. A saliva stone weighing 93 Gm. has been excised by Throwgood. One of the two stones was yellowish, the other gray; one soft, one hard. Their composition was calcium carbonate 10 per cent, calcium phosphate 30 per cent and organic matter 10 per cent. Saliva stones are found either in the salivary glands or in the salivary canal. Experiments have shown that the p_H of saliva during the day is 6.5 to 6.9 and during the night is slightly lower. According to Brickman, the average p_H is from 5 to 8. Experiments made on 50 patients at the department of jaw surgery at the Gülhane Hospital in Ankara showed that the p_H of the saliva of 2 patients was 6; of 10, 6.5; of 7, 7.1; of 15, 7.5, and of 16, 8.

Saliva stones are rare in Turkey. It is possible that afflicted persons fail to consult a physician; however, there is little concerning saliva stones in Turkish medical literature.

Anniversary of Child Welfare Society

The Turkish Child Welfare Society, a gift of the republican government, has since its incorporation in 1923 been directed by Dr. Fuad Umay, M.P. There are branches in all parts of the country with headquarters in Ankara, to which donations, gifts and contributions of the 100,000 members are forwarded. The society derives its income from various sources. During child welfare week, which begins on April 23, the national holiday, and all other national and religious holidays, a small tax stamp is affixed to all outgoing mail and special cable forms are issued; bazaars and children's balls are given at certain seasons in a number of towns; there are voluntary contributions in the form of special stamps to be affixed to documents or transportation tickets; rent is obtained from buildings in Istanbul and Ankara owned by the society; funds are allocated from the government budget, from municipalities and private administrations; the organization of lotteries, plays, national dances, sports and races also augments the income. The society receives in addition contributions from abroad, especially from Turkish people living in the United States, who donate considerable sums every year.

The one hundred bed modern children's home for foundlings, orphans and other poor children is directed by pediatricians, and a school for the training of children's nurses is attached to the home. The society has also established free dental clinics for children; dispensaries, policlinics, soup kitchens and bathhouses for children and their mothers, and swimming pools for the use of children only.

Established and operated by the society are twenty-eight children's homes, twenty-one nursery schools, three maternity homes, thirty-six soup kitchens, six homes for poor pupils, nine bathhouses and swimming pools, forty-four dispensaries for mother and children, fifteen free milk dispensaries for babies' formulas, three dental clinics, free school lunch programs in ninety-nine schools, five children's libraries and sixty-six modern playgrounds.

Persons who have promoted the work of the society are presented with a bronze, silver or gold medal. Twins, triplets and quadruplets born to poor mothers are taken under the protection of the society. The mother is given a monetary reward, is provided with free milk and is sometimes presented with a milch cow.

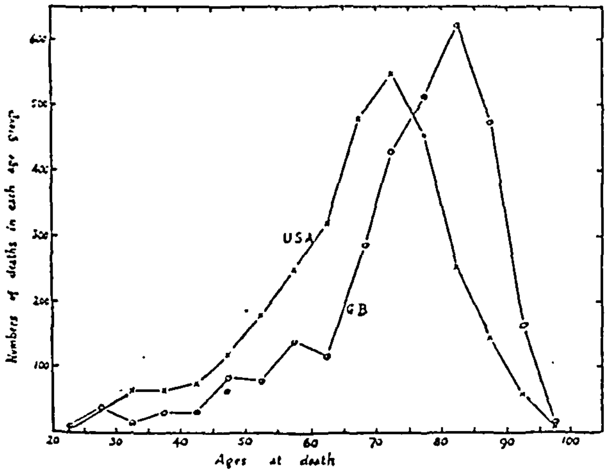
Correspondence

COMPARISON OF DEATHS AMONG PHYSICIANS IN UNITED STATES AND GREAT BRITAIN

To the Editor:—The Analysis of deaths among physicians in the United States for the year 1947 (The Journal, January 24, p. 252) prompted a similar analysis of British figures. We had in mind the possible effects of the more even tenor of English life and the effects of the "austerity" on those inclined to excess weight with its attendant dangers and diseases.

The accompanying graph was constructed from an analysis of the 3,040 deaths during 1947 referred to in The Journal and from 391 deaths of British physicians culled from the obituary columns of the *Lancet* from July 1945 to December 1947. In only about half of the British physicians listed were the ages at death stated, and it is possible that this group is not representative.

For comparison the British figures were recalculated to show what they would have been had the total deaths been raised from 391 to 3,040. For whatever it may be worth, the graph shows that the British have, in proportion, two or three times as many physicians reach the age of 80 and over as do the United States. The peak of the British curve is about one decade higher than the American. Some comments from readers might be interesting.



Comparison of ages at death of physicians of the United States and of Great Britain.

Phebe Hoff, M.A., and Frank L. Apperly, M.D.
Richmond, Va.

INTRAOCULAR FOREIGN BODIES

To the Editor:—In the Dec. 6, 1947 issue of The Journal of the American Medical Association, page 894, Dr. George Haik makes an excellent contribution in his article on "Intraocular Foreign Bodies." Due to education and safety devices, fortunately, intraocular foreign bodies are not as frequently encountered as they were during the early part of the century. The late Dr. George Sloan Dixon of the New York Eye and Ear Infirmary told me that when he was pioneering in roentgen localization there were always several patients to be examined roentgenologically each day. Now weeks go by without even 1 case being seen. With the decrease in cases has come need of articles like that of Dr. Haik to make up for lessened experience among eye surgeons.

Dr. Haik emphasizes need of accurate localization of intraocular foreign bodies. Until the advent of the Berman and Carney locators this had to be done only by roentgen ray. (The Carney locator I have never seen.) The various technics of roentgen localization take special skill, which unfortunately is not available in most communities. The Berman locator and presumably the Carney locator can be used by a surgical team without aid from another department of a hospital or a different set of specialists. All the work can be done in an operating room. These locators are available immediately for emergencies, day or night, Sundays, holidays and week days. One does not have to summon the roentgenologic group, wait for plates to dry and for interpretation and charting. With the Berman locator the surgeon can get instant pinpoint localization.

Probably Dr. Haik was not aware that the Berman locator can detect nonmagnetic as well as magnetic foreign bodies. In addition in magnetic foreign bodies it furnishes valuable information ahead of time of how much magnetic force will be needed to extract a magnetic foreign body. Dr. Haik calls attention to the dangers of using too much force, and he correctly warns against diagnostic trials with the magnetic extractor.

It seemed to me that Dr. Haik overemphasized delay in removing intraocular foreign bodies. During the past three years I have been successful in removing intraocular foreign bodies within an hour after hospital admission. Localization was performed by the Berman locator in my office before the patient was sent to the hospital, and extraction was performed with the aid of another Berman locator in the operating room. Roentgen films were often not taken for a week or ten days and were then taken only to have a tangible record. I think all patients with intraocular foreign bodies require emergency treatment, and now with the aid of the Berman locator they can receive the attention they deserve.

Loren Guy, M.D., New York.

LABELING PROTEIN PREPARATIONS

To the Editor:—A curious oversight appears to be common in biochemical and medical literature and in the trade customs of labeling protein preparations; it arises from considering the protein portion of a nutritional preparation to yield protein for both tissue building and energy production. For example, a unit of a nutritional product containing 50 Gm. of protein is considered to provide 50 Gm. of protein and 200 calories (4 calories per gram of protein). This may be misleading, for if all the protein is efficiently used to form tissue protein, no calories can be provided by it; conversely, if each gram of the protein is to produce 4 calories, the protein must be completely burned and thus can form no tissue protein. The number of calories actually furnished by 1 Gm. of protein will range from 0 to 4; the more efficiently the protein of the product is utilized to synthesize tissue protein, the fewer calories will be furnished.

Of nine protein or protein hydrolysate preparations selected at random, seven were found to make claims for caloric equivalents, all apparently based on the assumption that each gram of protein yields approximately 4 calories. Since all these preparations are intended to supply their protein component for protein anabolism, it seems inconsistent to imply that the same protein is also available for calorie production.

A second, though less important, assumption is that protein hydrolysates are equal to protein in caloric value, but the approximation involved here is in general acceptable.

It is suggested that protein preparations intended to provide protein for tissue-protein synthesis should not be claimed to have caloric value except as the latter is provided by added constituents of the type actually burned in the body. Ordinarily, these constituents will be carbohydrate and fat only.

MEDICOLEGAL ABSTRACTS

Food and Drug Acts: Evidence of Misbranding of Device.—The United States filed a libel against sixteen Sinuothermic machines, owned or manufactured by the claimant, on the ground that they were misbranded when shipped in interstate commerce. The misbranding was alleged to have consisted of printed matter accompanying them which represented that the machines had a therapeutic value in the diagnosis and treatment of stated diseases of man, whereas the devices were not effective for such purposes. From a judgment of condemnation and destruction, the claimant appealed to the circuit court of appeals, fifth circuit.

The federal law prohibits the introduction into and the receipt in interstate commerce of any food, drug, device or cosmetic that is adulterated or misbranded and provides for seizure and condemnation of such. It is not denied that these machines were devices within the act. A drug or device shall be deemed to be misbranded, within the federal act, if its labeling is false or misleading in any particular. The term "labeling" means all labels and other written, printed or graphic matter on any article or any of its containers or wrappers or accompanying such article. The last three words, said the court of appeals, are critical here. They make the term "labeling" broader than "label," which includes only what is displayed on the immediate container of an article. How much broader? The sixteen devices in question were shipped in several consignments from a place in Florida to a designated place in Ohio. The first three shipments went forward and were received by the proper party and put to work in his medical practice several weeks before any leaflets were sent. They did not accompany any of the devices while they were in interstate commerce. The last of the shipments went forward three weeks after the leaflets and was not accompanied by them. Accompany, said the court, means to go along with. In a criminal and forfeiture statute the meaning cannot be stretched. Furthermore, it may be doubted, said the court, that the printed matter is in its nature a labeling for the machines. It looks like a small newspaper, entitled "The Road to Health, by Dr. Fred Urbeteit. Every subject pertaining to Health, Doctoring and Nursing is being taught at the College of Sinuothermic Institute, Inc., 307 West Euclid Ave., Tampa, Florida." To the left of this heading is a picture of Dr. Fred Urbeteit, president of Sinuothermic Institute, Inc., and to the right an attractive picture of the institute and its grounds. Fifteen columns of fine print are below, consisting of testimonials and case histories of patients who had been treated at the institute by Dr. Urbeteit, with unstinted praise of both. The Sinuothermic machine is mentioned and praised as an instrument of diagnosis and treatment, but there is no description or picture of the machine, no explanation of its operation and no suggestion that it is for sale. The whole thing, said the court of appeals, appears to be an advertisement for the institute and Dr Urbeteit, rather than something to accompany machines. Whether we ought to hold it a labeling of these machines if shipped simultaneously with them, the court continued, may be doubted. But if it could be called labeling, it is not proved by the present skimpy evidence that it accompanied the machines or any one of them while they were in interstate commerce.

The claimant vigorously contended that all he had said in "The Road to Health" was true. He offered in his claim, since no employee of the United States and only a few practitioners whom he had instructed, had any actual knowledge of his machine, to conduct a series of tests of it in cooperation with practitioners of medicine, osteopathy, chiropractic and naturopathy approved by the court, preferably on persons previously treated by medical practitioners without success, they to be examined before and after the test by physicians appointed by the court during such period as the court should fix, the physicians' determination of the results to be evidence in the case. This was not done. Dr. Urbeteit at least seems convinced of the efficacy of his machine, said the court of appeals. He testified in detail as to each case mentioned in "The Road to Health." He had present 30 of his patients, whom he offered as witnesses to the benefits they had received, many of them being those mentioned in "The Road to Health." The trial judge refused to hear them on the ground that, being laymen, they could not testify as to what was the matter with them and consequently could not say what they were relieved from, and that the diagnoses testified to by Dr. Urbeteit could not be accepted because he rested them on the use of his machine which the government's witnesses, who were men of high standing in medicine and in the electrical arts, had testified could not do what Dr. Urbeteit claimed. These rulings, said the court of appeals, were error. One was based on the idea that Dr. Urbeteit had made his diagnoses solely on the indications of the machine. But his testimony as a whole was that he used all known methods of diagnosis, that the machine did not indicate any particular disease but only located the spot where the abnormal tissue was, and that it was then a matter of judgment as to what the disease was. He only claimed the machine to be an aid in diagnosing. The patients themselves, said the court, could certainly know whether their external symptoms abated and their pains ceased. Urbeteit, being a licensed doctor of some twenty years' practice, could express expert opinions. The judge might, continued the circuit court of appeals, after hearing all the evidence, prefer the expert opinions of the government witnesses to those of Dr. Urbeteit, even as against the facts to which he and his witnesses might swear, but the judge should have heard all the competent testimony before making up his mind. The most eminent physicians and scientists have in the past erred in their opinions, and opinions generally must yield to well proved contrary facts. The case, the court concluded, ought to have been more fully tried. Accordingly, the judgment in favor of the government was eversed and the cause was remanded for further proceedings.—*Urbeteit v. United States, 164 F. (2d) 245 (1947).*

COMING EXAMINATIONS AND MEETINGS

BOARD OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL March 6, page 713.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I & II.* Various centers, June 21-23. Final date for filing application is May 22. *Part II.* Various centers, April 26-27. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral.* New York, April 12-15 Sec., Dr. Paul M Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Oct. 18. Final date for filing application is June 1. Asst. Sec-Treas., Dr. W. A. Werrell. 1 West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* June 1949 Final date for filing application is Feb. 1, 1949. Sec., Dr. W. J. German. 310 Cedar Street, New Haven, Conn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Oral. All Groups. Part II.* Washington, D. C., May 16-22. Final date for assignment is April 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY. *Oral.* Baltimore, May 20. Chicago, Oct. 6. *Written.* Various centers, Jan. 1949 Final date for filing application is July 1, 1948. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Part II.* Chicago, January 1949. Final date for filing application is August 15. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

AMERICAN BOARD OF OTOLARYNGOLOGY. *Oral.* Chicago, June 15-19. Sec., D. M. Lierle, University Hospital, Iowa City, Iowa.

AMERICAN BOARD OF PATHOLOGY. Philadelphia, March 8-10 Final date for filing application is March 1 Sec., Dr. Robert A. Moore, 507 Euclid Ave., St Louis, Mo.

AMERICAN BOARD OF PEDIATRICS: *Oral.* Cleveland, April 23-25. Chicago, June 25-27. Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. *Written.* March 12 July 30. Sec., Miss Lea Leonard, 718 Royal Union Bldg., Des Moines, Ia.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr Robert H. Ivy, 1930 Chestnut St., Philadelphia.

AMERICAN BOARD OF SURGERY: *Written. Part I.* October. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Travel in Pregnancy. W. B. Beach Jr.—p. 1054.

Precursors of Corpus Carcinoma.—Gusberg reports on the endocrine-tumor relationship in four groups. The endometrial hyperplasia produced by granulosa cell tumors and the accumulating evidence of association of estrogen-producing ovarian tumors with carcinoma of the corpus uteri, together with data obtained from study of the pattern of adenomatous hyperplasia produced in such cases, are suggestive of an estrogen-cancer relationship. The second group studied concerned human endometrium with advanced degree of hyperplasia produced by prolonged administration of estrogens. None of these endometriums could be called malignant, but all appeared very active, and some varied sufficiently from the well known pattern of cystic glandular hyperplasia so as to convince both pathologist and clinician that the patient's interests would best be served by prophylactic hysterectomy. With regard to the third group, adenocarcinoma of the human endometrium following prolonged administration of estrogens, it appears that in spite of the common use of hormonal therapy for menopausal symptoms in recent years there have been few reports of resultant uterine carcinoma. The author presents the histories of 5 patients in whom adenocarcinoma of the corpus uteri developed after prolonged administration of estrogens, and 3 carcinomas of the corpus and an ovarian adenocarcinoma the development of which may have been accelerated by administration of estrogens and their histologic pattern modified. Studies in the fourth group concerned endometrial patterns in patients with recurrent episodes of "functional bleeding." The well defined histologic pattern recurring in these related groups of tissues suggests that endogenous or exogenous estrogens play a role in the development of carcinoma of the corpus uteri.

Fatal Eclampsia.—Way reviews 33 fatal cases of eclampsia which were subjected to necropsy. Analysis of the clinical histories has been presented in relation to age, parity, race, prenatal care, family history, previous medical and obstetric history, symptoms, physical findings on admission, duration of pregnancy, chemistry of the blood and duration of hospital stay prior to death. Hepatic lesions consisted of focal fibrinoid necrosis, with or without hemorrhage. Renal lesions have been divided into three stages which represent steps in the development of permanent renal change: Stage 1, with glomerular but without arteriolar alterations, was typical in 33 per cent of the cases; stage 2, characterized by thickening of the arteriolar wall, was observed in 48 per cent of the cases, and stage 3, with lesions similar to arteriolonephrosclerosis, characterized 18 per cent of the cases. Eleven patients had hemorrhage and necrosis in the adrenal glands. Additional lesions found were: pneumonia; focal necrosis of the myocardium, pancreas and brain; acute endometritis; cerebral hemorrhage; cystitis; acute mastitis, and cerebral arteritis and *arteriolitis. An attempt is made to correlate the observed* lesions with some current hypotheses concerning the pathogenesis of eclampsia.

Anticoagulation Therapy in Puerperium and Gynecologic Surgery.—Greene and Loewe say that during the past three years 251 patients with venous thromboembolic disease received heparin subcutaneously in the Pitkin menstruum (gelatin 15 to 30 per cent, dextrose 5 to 12 per cent, glacial acetic acid 0.5 per cent, and distilled water) with gratifying results. Fifty-three of these 251 subjects were obstetric or gynecologic patients. The treatment of venous thromboembolic disease with subcutaneous heparin in the Pitkin menstruum was attended with lessened morbidity, prompt and rapid clinical improvement, and little or no residual edema. The causative factors responsible for the one treatment failure have been analyzed. Treatment failures with other methods responded with recovery after the routine administration of the heparin/Pitkin menstruum preparation. The subcutaneous administration of heparin in the Pitkin menstruum is recommended as a safe, simple, practical and effective method for anticoagulation therapy in thromboembolic disease complicating the puerperium and gynecologic surgery.

Cervical Cancer in Young Girls.—Speert presents 2 cases of cervical carcinoma in girls aged 12 and 19 years, respectively. Case 1 is the seventh reported instance of carcinoma of the cervix in girls age 12 or under. In contrast to the preponderance of epidermoid cervical cancer in adult women, adenocarcinoma is the commonest type of cervical carcinoma in young girls. The poor prognosis associated with cervical cancer in young girls in the past may be the result of inadequate treatment.

Technical Methods for 1/2,000 Field. M. Chamlin.—p. 1415.
Clinical Use of Di-Isopropyl Fluorophosphate (D.F.P.) in Chronic Glaucoma. W. G. Marr.—p. 1423.

Mascara Causing Pigmentation of Palpebral Conjunctiva.—Reese observed a granular, stippled pigmentation under the palpebral conjunctiva of both upper lids of a middle-aged woman. *The nature of the lesion was not recognized at first.* The condition showed no appreciable change after ten months. The pigmentation was situated at each extremity of the tarsus on a level with its upper border. It was located under rather than in the conjunctiva. Over the pigmented area there was a folliculosis and slight congestion. The condition was identical in both lids. After two and one-half years, there had been some extension of the pigmentation. It could be seen as a narrow line along the upper border of the tarsus, fading out in the central portion. In addition, a mottled, deep-seated, bluish black pigmentation could be seen under the conjunctiva of the lower lid. During the period this case has been followed, 6 additional cases have been observed. The symptoms referable to the condition are mild. There may be burning, redness and itching of the eyes, sleepiness, roughness and swelling of the lids, and desire to blink the eyes excessively. All the patients were women, 5 of whom admitted the constant use of mascara. It is concluded that the pigmentation of the palpebral conjunctiva results from the use of mascara or allied pigment-bearing cosmetics but that there is some factor peculiar to the individual determining its occurrence, because this pigmentation does not develop in everyone who uses mascara.

Serum Concentrations of Penicillin.—Hewitt presents pharmacologic data concerning absorption of sodium and potassium salts of crystalline penicillin G suspended in a mixture of peanut oil and beeswax. Most of the subjects studied were normal postpartum women or young adults convalescing from various types of acute illness. Administration of 300,000 units of crystalline sodium penicillin G in peanut oil and beeswax produced demonstrable concentrations of penicillin in the serum at twelve hours after administration in practically all cases and at twenty-four hours after administration in 70 per cent of cases. A single injection of 600,000 units of crystalline sodium penicillin G in peanut oil and beeswax produced assayable concentrations of penicillin in the serum twenty-four hours after administration in 86 per cent of cases. Equal division of a given dosage of penicillin in peanut oil and beeswax between two sites and simultaneous injection produced higher maximum levels during the first eight hours after administration but resulted in a shorter duration of assayable concentrations of penicillin in the serum. The volume of peanut oil and beeswax in which a given dosage of penicillin was administered did not affect appreciably the height or duration of the serum concentration. Division of a daily dose of penicillin into two injections given at twelve hour intervals rather than in a single daily injection resulted in maximum levels of lower magnitude, but insured a more uniform concentration of penicillin in the serum at all times than with the employment of a single daily dose.

Precautionary Administration of Penicillin in Surgical Procedures on Bones and Joints. J. Buchman and J. E. Blair.—p. 743.

Control of Arterial Hemorrhage.—Jenkins and his associates attempted to control arterial hemorrhage with the gelatin sponge patch. All of the 22 dogs on which the authors made their experiments survived the immediate postoperative period. In 5 animals in which the gelatin sponge "cuff" alone was used to control hemorrhage from a wound of the aorta, a blowout occurred in 2 and caused death from massive retroperitoneal hemorrhage. The other animals in this series died on the second, third and sixth days after operation from distemper and pneumonia. There was no evidence of secondary hemorrhage in these animals, and the lumen of the vessel was found to be patent. The gelatin sponge cuff was rather badly fragmented, especially where the sponge was held by sutures. In the 16 animals in which the gelatin sponge "cuff" was supported by a sheath of chromic surgical gut there was only one blowout from the arterial wound. Six animals died from distemper and pneumonia, or were killed, on the third, the sixth, the ninth, the tenth, the eleventh and the fourteenth day. The sponge "cuff" and sheath were found to be intact, and the lumen of the vessel was patent and free from thrombosis. Eight animals survived for longer periods and were killed. The location of the wound in the vessel wall could be detected as a white scar which was apparently well healed over. The authors conclude that the gelatin sponge cuff and chromic surgical gut sheath offer a new method which may have a clinical application such as in the emergency treatment of wounds of major arteries, where one may not be in a position to do a careful arterial suture, and as a "secondary line of defense" against blowouts where arterial suture has been performed for a wound of the vessel or for anastomosis.

Chemotherapy in Gas Gangrene.—Altemeier and his co-workers produced infections with gas gangrene in animal experiments by inoculating bacterial cultures through hypodermic needles into healthy muscle. Infections produced under such conditions are different from those occurring in the clinic. This difference is largely responsible for the discrepancy between the obvious effectiveness of penicillin in gas gangrene experimentally produced and its questionable value in the type occurring clinically. A standardized experimental gas gangrene s now produced in the presence of crushed muscle and dirt, thus closely simulating conditions of the clinical type. Guinea pigs were chosen as the experimental animals, because of their pronounced susceptibility to infection with Clostridium welchii, which resembles that of human beings. Streptomycin was found to have no significant therapeutic value. Penicillin had a notable beneficial effect on the rate of development and the extensiveness of the infection as well as on the mortality. Since the effect of chemotherapy was greatly modified by the time of onset and the size of the dose, it would seem advisable to administer penicillin parenterally as soon as possible and in conjunction with surgical treatment in persons with gas gangrene or with wounds of the type which predisposes to its development and to continue using it thereafter in doses up to 1,000,000 units every three hours until the threat of this infection is over.

Postmastectomy Swelling of Arm.—Hanelin and his collaborators review observations on 25 patients with this disorder. Injection of 5 cc. of a 1 per cent solution of procaine hydrochloride into the stellate ganglion at periodic intervals will help to relieve symptoms referable to swelling of the arm following mastectomy. They employed this treatment in 21 of the 25 patients. Nineteen reported that they were benefited by the treatment. Of the 4 control patients who did not have a paravertebral block and who were observed for the same period (six months), none exhibited any improvement of the arm as compared with those who had it one or more times. Improvement of the circulation and the mobility of the involved arm subsequent to the paravertebral block are definite steps forward. The clinical improvement seems dependent to a great extent on the number of times paravertebral block is carried out; the more frequent the block, the more persistent and prolonged the response. The authors speculate on the advisability of doing sympathectomies for permanent reversal of this phlebospastic state.

Poliomyelitis in Cincinnati in 1946. J. A. Browning.—p. 724.
Homologous Serum Hepatitis: Clinical Implications. L. Schiff.—p. 736.

Homologous Serum Hepatitis.—Schiff emphasizes the importance of homologous serum jaundice in the differential diagnosis of jaundice, with particular respect to (1) metastatic neoplasm of the liver in patients who have had a recent resection of a malignant tumor, (2) stricture of the common duct (or sometimes stone) in patients who have had a recent operation on the biliary tract, usually a cholecystectomy and (3) neoplasm as a cause of painless jaundice in middle-aged or older persons. He cites histories to illustrate these three problems and lists the important data of the 6 cases presented. He and his 2 associates have seen 11 cases of serum jaundice in a little more than a year. They believe that many cases are overlooked because the condition is not usually considered in the differential diagnosis of jaundice. It is rather probable that needless operations have bee n performed on this account. It is essential that the physician keep homologous serum jaundice in mind whenever he sees a patient with icterus, regardless of the age of the patient, particularly if there is a history of an illness or an operation two to five months before the development of jaundice, even if the operation was performed on the biliary tract. His suspicions should be confirmed by recourse to the cephalin cholesterol flocculation and thymol turbidity tests.

Megaloblastic Anemia in Infants.—According to Aldrich and Nelson there exists a syndrome of macrocytic anemia in infants which is not uncommon and which may easily be mistaken for pernicious anemia on the basis of blood morphology alone. Zuelzer and Ogden considered this anemia to be a distinct entity, and have suggested naming it megaloblastic anemia of infants. During an eight month period Aldrich and Nelson observed 6 infants ranging in age from 6 to 9 months who presented the typical syndrome of infantile megaloblastic anemia. Zuelzer and Ogden regarded this anemia as the result of deficiency of a hemopoietic factor derived from "folic acid" or purified liver extract. The disease differs from pernicious anemia in adults by the complete and lasting cure effected, no relapses having been observed. Whereas Zuelzer and Ogden considered infection and nutritional deficiency as possible etiologic factors, the experience of Aldrich and Nelson places emphasis on nutritional factors. The diets of their patients were uniform in composition and regularly deficient in ascorbic acid. The fact that megaloblastic anemia has developed with a wide variety of diets points to a combination of factors which may cause a deficiency in some hemopoietic principle. The discovery of 6 cases of infantile megaloblastic anemia in the short period of eight months in one clinic indicates the necessity of the physician's being on the alert to recognize this type of anemia in infants.

Bronchiectasis.—Badger says that in 400 cases of bronchiectasis treated in the Massachusetts General Hospital, 59 per cent were unsuitable for surgical treatment and other observers say that about 50 per cent of patients with bronchiectasis are unsuitable for surgical treatment. The patients not suitable for surgical treatment are those with too much or too little bronchiectasis, those with limited cardiovascular reserve, those with limited pulmonary reserve because of associated emphysema, those with concurrent disease and those who will not submit to surgical treatment. Asymptomatic bronchiectasis does not require excision. About two thirds of all cases of bronchiectasis, with or without surgical treatment, require medical supervision and care. The medical management of bronchiectasis is directed toward mechanical drainage, control of infection, measures to improve the general health of the patient and the prevention of the condition before it occurs. The author regards postural drainage as the most important single mechanical procedure for emptying dependent bronchiectatic cavities of their secretions. Bronchoscopy remains an important procedure in bronchiectasis, and a necessary one in cases presented for surgical treatment. Chemotherapy in any form has so far provided no cure for bronchiectasis, but its judicious use in conjunction with mechanical drainage can make life bearable for many patients with severe bronchiectasis and can shorten the duration of the acute attacks of bronchitis and pneumonitis in milder cases. Improvement of general health requires good nutrition, rest, exercise and avoidance of lasting fatigue. Smoking may irritate a respiratory mucosa already inflamed with infection. Avoidance of exposure to cold and wet and sleeping in warm fresh air, rather than freezing cold drafty rooms, are of value to those who are sensitive to acute respiratory diseases. Prevention takes two major directions. The first is early diagnosis of bacterial pneumonias, with adequate chemotherapy. The second is reexpansion of atelectases that persist after pneumonias and acute respiratory infections, especially in children.

Esophageal Stricture Following Agranulocytosis.—Bryan reports the case of a woman, aged 38, in whom severe esophageal stenosis developed following agranulocytosis due to sulfonamide therapy. It is assumed that the same ulcerative process that caused the severe angina of the mouth caused ulcers in the esophagus and that, after the acute esophagitis had resolved, secondary cicatricial stenosis took place. Had the nature of the process taking place in the esophagus been appreciated sooner, bouginage at an earlier date might have prevented the resulting stenosis.

Family Outbreak of Lead Poisoning.—The outbreak reported by Spizer concerned a family of 6 who lived in a shack with a stove and an open fireplace. The father, aged 30, the mother, aged 24, and 4 children, twins, a boy and a girl aged 3, a girl aged 2 and a boy aged 1, had all been in good health previously. The child of 2 years became ill with symptoms of coryza and diarrhea, then had convulsions and died. The twins, aged 3, and the boy aged 1 also became ill. Because of the familial character of the outbreak and the history of diarrhea, the tentative diagnosis on admission was possible shigellosis. With the discovery of stippled red blood cells the diagnosis of lead poisoning came to the fore. Treatment directed at immobilizing the lead was begun promptly. The children were given a diet high in calcium with a high ratio of phosphorus to calcium. This included a quart of milk a day. Vitamin D was given in the form of calciferol, 5,000 units daily. The children also received calcium lactate and sodium citrate. The twins and the year old boy were discharged in apparent good health after fifteen and ten days, respectively. The parents, who remained free from lead poisoning, were queried regarding possible sources of lead poisoning, and it finally came to light that storage battery casings had been used for fuel in the room in which the children slept. The authors cite literature on this source of lead poisoning and stress that children are more susceptible to lead poisoning than are adults.

Failure Following Disk Operations.—Campbell and Whitfield reexamined a series of 122 patients operated on one to nine years previously for removal of a ruptured intervertebral disk. On the basis of absence of pain and ability to return to their original work, 68 patients were classified as having obtained "excellent" results. The results in 33 patients were termed "good" because they were doing lighter work without pain or the same work with some discomfort and in 21 patients "poor" since they had not returned to work and since they complained either of pain or of motor weakness which prevented their resuming their usual activities. It is of significance that 19 of these 21 patients came under Workmen's Compensation while 13 were considered before operations to be poor psychologic risks. In some instances, however, the reasons for failure were persistent neurologic defects, such as motor weakness and obvious pain. At least 3 or 4 of this group had recurrences, but they have refused further procedures thus far. It is noteworthy that certain persistent postoperative neurologic defects, such as absent or diminished knee or ankle jerks or persistent areas of hypesthesia or even anesthesia, do not necessarily preclude an "excellent" or "good" result. One should operate only on those patients who cannot get along with conservative treatment, and, if operation be performed, it should be carried out at a time when the patient is having pain or disability rather than when he is in a remission. It is also of great importance that the patient operated on is anxious both to get well and to work again.

Streptomycin in Tuberculosis.—Willis reviews the present status of streptomycin in the treatment of tuberculosis. In spite of the fact that 1,500 cases have been studied to date, no one knows what the drug really does in tuberculosis of many parts of the body—particularly the lymphatic system, the bone, the eye, the genitourinary tract, the skin and many types of pulmonary tuberculosis. Streptomycin should be used in miliary tuberculosis, tuberculous meningitis, tuberculous sinuses and fistulas and certain cases of "early" tuberculosis known to have been present only a few days or weeks. The drug should not be used in the average case of chronic fibrous or cavitary tuberculosis. It should not be given to patients unless the functional capacity of the kidneys is known to be normal. It should always be reckoned as an adjunct to the accepted measures of bed rest and collapse therapy, and never as a substitute for these. Since it is given to patients with active disease, it is highly desirable that the patient be in a sanatorium during treatment.

Subarachnoid Hemorrhage.—Ungerman and Lowbeer review the present status of knowledge on subarachnoid hemorrhage and stress that it is a symptom and not a disease entity. In the vast majority the hemorrhage is due to a rupture of an intracranial aneurysm, particularly of the circle of Willis; arteriosclerosis, septic or infectious embolism, trauma, massive cerebral hemorrhage, intraventricular hemorrhage, blood dyscrasias, vascular cerebral neoplasm, postoperative focal necrosis of cerebral vessels, complication of encephalography, shock therapy and artificial hyperpyrexia contribute a small number of cases. The syndrome is usually characterized by the sudden onset of headache, nuchal rigidity, mild Kernig sign, vomiting, various degrees of hyperemia of optic disks, involvement of one or several of the cranial nerves, frequent changes in pupillary reactions, mild leukocytosis, mild elevation of temperature and slow pulse; the spinal fluid is under pressure and uniformly bloody with an xanthochromic supernatant fluid. Symptoms referable to irritation of various nerve roots, particularly those making up the lumbosacral plexus, may be present. The onset is sudden. Treatment is directed toward relief of headache, reduction of intracranial pressure, alleviation of excitement and adequate feeding. Subsequent surgical measures can be considered in suitable cases of aneurysmal rupture. The authors report 2 cases of confirmed spontaneous subarachnoid hemorrhage in which the initial symptoms resembled Dietl's or renal crisis. One of the authors performed necropsies in 6 cases of fatal subarachnoid hemorrhage. All were caused by rupture of an aneurysm of a basal cerebral artery. The diagnosis of syphilitic aneurysm was made in 2 cases, that of congenital aneurysm in 1 case and that of arteriosclerotic aneurysm in 3 cases. The authors think that syphilis plays a more important role in subarachnoid hemorrhage than is generally believed.

Methadon for Pain in Bone and Joint Disorders.—The control of pain in diseases of the bones and joints has always been a serious problem. The tendency toward chronicity of the diseases and injuries to the skeletal system and the ever-present danger of addiction prevents many physicians from adequately relieving the pain of these patients. Ishmael and Stacy give a brief outline of the pharmacologic and clinical nature of the drug methadon ("dolophine" or "amidon") and report on the effectiveness of this analgesic in 106 orthopedic and arthritic patients treated in hospitals in Oklahoma City. The dosage was 2.5 mg. given orally every four to eight hours. This dose was needed as frequently as every two hours in a few cases and as infrequently as every twenty-four hours. In a few instances the drug was used hypodermically. The conditions for which the drug was administered included sciatica, rheumatoid arthritis, periarthritis of shoulder, causalgia, osteoarthritis, carcinomatosis, spondylitis, sacral pain, fractures and others. Some of the patients did not experience relief, but the impression was gained that the type of disorder has less to do with the efficacy of the analgesic than does the constitutional make-up of the patient. Some tolerated methadon who did not tolerate morphine or codeine. The authors conclude that methadon is a satisfactory analgesic for use in the control of pain of bone and nerve root. Its chief use is in patients whose pain is too severe for acetylsalicylic acid and too chronic in nature for morphine. The possible danger of habituation should be borne in mind until extensive clinical trial establishes whether this drug is definitely habit forming.

Vagotomy in Peptic Ulcer.—Cole and his associates discuss the status of vagotomy in the treatment of peptic ulcer on the basis of their own observations and reports in the literature. They think that good results will be obtained in 80 to 90 per cent of patients. Vagotomy appears to be particularly effective against gastrojejunal ulcer. Gastric dilatation, diarrhea, persistent or recurrent ulcer, thoracic pain (following transthoracic approach) and vagovagal reflex have been reported as complications of the operation. Gastric dilatation is reported as being one of the most frequent complications, although the authors noted it in only 10 per cent in their 30 cases. Gastric retention is common after vagotomy. In 2 patients of the authors' series so much obstruction developed that gastroenterostomy was necessary. Prolonged gastric decompression for three to six days will decrease the incidence of gastric retention. Elimination of gastric retention in all patients cannot be expected because obstruction may result from the ulcer scar if gastroenterostomy was not performed at the initial operation. It may be advisable to perform a gastroenterostomy along with vagotomy when the ulcer is large. The most serious reaction is cardiac and respiratory paralysis arising from vagovagal reflex; it may result in a fatality but fortunately is rare. The mortality rate should be less than 1 per cent. The authors have had no deaths in their series of 30 cases with 12 gastrectomies. It is probable that gastric resection is not necessary in such a large percentage of cases. The authors prefer the transabdominal operation but emphasize that if this approach is utilized meticulous search must be made for branches of the two vagus nerves, as they found three or more major vagus trunks in 90 per cent of their patients. Although results have been good, wholesale adoption of the procedure for all types of cases must not occur until sufficient time has elapsed for a correct appraisal of the permanent results.

Sulfamerazine for Pneumonia.—Joules and Weller say that there is a tendency to regard the sulfonamide drugs as superseded by penicillin not only in the severely ill but even in mild conditions where the former have proved adequate. They show that sulfonamide treatment for primary pneumonia in adults is satisfactory in the vast majority of cases and should be given before confirmation of a clinical diagnosis. The authors reviewed the last 189 proved cases of pneumonia, that is, those occurring since sulfamerazine became easily available. Cases in which pneumonia occurred as a terminal event in another mortal illness are excluded. Of 189 patients, 113 were treated with sulfamerazine from the start without a single death; 36 were treated with sulfamezathine (2-sulfanilamido-4-6-dimethyl pyrimidine) with 3 deaths, and 22 with penicillin with 1 death. Combined treatment was given to 12 patients, 1 of whom died. The remaining cases were so mild that no specific therapy was deemed necessary. The authors stress that sulfamerazine, which can be given in relatively small doses at intervals of eight hours, is a satisfactory therapeutic agent. The results are such that pneumonia can be treated at home and be reduced to a "two day fever." If there is no response within forty-eight hours the case should be reviewed at once and the facilities provided by the hospital for further investigation and treatment should be employed. The need for radiologic demonstration of complete resolution of the disease is emphasized, as is the need for adequate convalescence. Sulfonamide treatment is less troublesome than penicillin therapy. With the newer sulfonamide preparations there is no need for frequent dosage, with consequent loss of sleep. Toxic effects are minimal, provided administration is not too prolonged.

Oral Penicillin in Pneumonia.—Anderson and Landsman investigated the efficacy of penicillin administered orally to an unselected series of male patients with pneumonia. The patients were classified in two groups, one group being given penicillin orally and the other penicillin intramuscularly. On admission they were allocated alternately to the two groups. The patients who received the penicillin intramuscularly were given an initial dose of 50,000 units, after which successive doses of 20,000 units were administered at intervals of four hours for five days. Occasional patients with severe infection received higher dosage in the early stages of treatment. The mean total dose of penicillin was 800,000 units. In the oral administration of penicillin tablets of calcium penicillin with 0.5 Gm. of sodium citrate were used, which contained 20,000 or 25,000 units of penicillin. The standard dose was 60,000 units at intervals of three hours, at least during the early stage of treatment. Administration was continued for five days. The mean total dose given orally was 1,650,000 units. Two measures were adopted in an endeavor to enhance absorption and to maintain effective levels of the drug in the blood: first, the tablets were always administered along with a small amount (1 to 2 ounces, 28 to 56 cc.) of milk; second, the daily fluid intake was reduced to 2 pints (946 cc.). The results indicate that the oral administration of penicillin is a satisfactory method of treatment for pneumonia. Experience would suggest that treatment should start with a daily oral dosage equal to four times that required by the intramuscular route. After obvious clinical improvement (usually within forty-eight to seventy-two hours) this dose may be reduced by half. The authors emphasize that the indications for penicillin therapy are not changed by the present report. The sulfonamide compounds constitute an adequate method of treatment for the majority of patients; but for those who require penicillin there may be some advantage in the use of the oral route. The difficulties associated with continued injections are overcome, and treatment of pneumonia with penicillin in the home becomes practicable.

The Dangers of Going to Bed.—Asher stresses that the physician should think twice before ordering his patient to bed. He shows that rest in bed involves dangers to the respiratory system, blood vessels, skin, muscles and joints, bones, renal and alimentary tracts and nervous system. The author also directs attention to the demoralizing effects of staying in bed but admits that there is much comfort and healing in rest and that rest in bed is essential in many illnesses. His chief object was to disclose the evils of excessive rest, and he indicates how some of them can be avoided or overcome. He comments on the favorable effects of early rising after operations. He thinks that one way to avoid the dangers of bed lies in altering the equipment and arrangement of a ward. There should be a day room attached to every ward and lockers for patients' ordinary clothes. Too often patients stay in bed because, shuffling around in slippers and dressing gown, they are cold and uncomfortable. More liberal attention should be paid to breathing exercises, moving the limbs, and occupational therapy.

Penicillin in Infectious Endocarditis.—Desbuquois and Binet treated 4 patients, 2 women aged 32 and 25, a girl aged 15 years and a man aged 64, with infectious endocarditis lenta with penicillin. In all patients several hemocultures were positive for green-producing streptococci. The patients had recurrent attacks of fever, and the general condition grew rapidly worse. Two had mitral valvulitis, the third had a congenital pulmonary stricture and the fourth had atheromatous aortitis with aortic insufficiency. In the first three patients complete recovery resulted from daily doses of 400,000 to 1,500,000 units of penicillin given for ten days to six weeks with total doses of 4,000,000 to 45,000,000 units. Drop in temperature of the three patients occurred on the tenth, twentieth and twelfth day of treatment, respectively, and was associated with considerable improvement of their general condition. Two patients presented symptoms of nephritis with albuminuria and azotemia which disappeared simultaneously with the symptoms of infection. There were two recurrences of the infectious syndrome in case 2; they may be prevented by prolonged treatment with massive doses of penicillin. Two of the patients presented a splenic embolism on the sixteenth and on the tenth day of treatment. It seems that embolism occurs more frequently in patients treated with penicillin. The drug had a favorable influence on the cardiac condition of the first 3 patients, but the fourth patient with atheromatous aortitis died on the twenty-sixth day after penicillin therapy was started; death resulted from a myocardial infarct. Recovery of young patients with infectious endocarditis may be obtained with massive doses of penicillin administered for sufficiently long periods in spite of occasional recurrences. The prognosis is less favorable in patients with a senile heart whose myocardium is deficient.

Autohemic Therapy and Penicillin in Phlebitis.—Hussenstein treated with autohemic therapy 4 women between the ages of 41 and 64 who were operated on for gastric ulcer, Pott's disease, generalized peritonitis resulting from pyosalpinx and neoplasm of the breast, and who presented premonitory symptoms of phlebitis or apparent postoperative phlebitis. Preventive treatment consisted of intramuscular injections of 20 cc. of blood on three consecutive days followed by injections of 20 cc. of blood every second day for ten days. In patients with apparent phlebitis 20 cc. of blood were administered on six consecutive days, after which injections were continued every second day until the edema disappeared. The occurrence of edema of the lower limb was prevented in patients who after the operation had pain in the groin or calf associated with rise of temperature and acceleration of pulse. Systematic use of autohemic therapy during the days after the operative intervention may prevent the appearance of phlebitis. In those instances in which autohemic therapy is instituted after the appearance of premonitory symptoms the phlebitis seems to have a benign and a shorter course, although it may be complicated occasionally by small embolisms. It is suggested that autohemic therapy may have an effect on the fluidity of the blood and on the coagulation time in addition to its desensitizing effect on the changes in the wall of the vein. One woman aged 25, in whom pelvic thrombophlebitis occurred two months after a normal delivery, was treated with penicillin; 600,000 units were administered on the first day, 400,000 on the second day followed by daily doses of 200,000 units until a total of 2,000,000 units were given. Complete recovery resulted from this treatment. One woman aged 45 who was operated on for subhepatic appendicitis with perivisceritis presented severe symptoms of phlebitis with temperature of 103 F. (39.5 C.) on the twenty-seventh postoperative day. Autohemic therapy was instituted and combined with penicillin; within seven days the patient was given 1,200,000 units of penicillin. Temperature was restored to normal by lysis and the edema slowly disappeared. A small embolism occurred on the twenty-second day of the phlebitis. Combined autohemic and penicillin therapy is indicated in cases of puerperal phlebitis and postoperative thrombophlebitis after gangrenous appendicitis, peritonitis or suppurative adnexitis. Autohemic therapy and penicillin treatment should be practiced along with the classic methods of treatment of phlebitis, i. e., early rising, anticoagulants and infiltration of lumbar ganglions with procaine hydrochloride.

Electroencephalography in Intracranial Tumors.—The material investigated by Buchthal and Busch comprises patients with surgically and pathologically verified cortical and subcortical tumors. Potential differences were led off from the intact skull with unipolar leads (the ear being used as reference electrode) and with bipolar leads, sixteen electrodes being distributed over the skull. For registration a three channel ink-writing electroencephalograph with differential amplifiers was used. In 60 verified intracranial tumors electroencephalography with unipolar leads indicated the affected hemisphere in 72 per cent, while 10 per cent were wrongly localized and 18 per cent could not be localized as to hemisphere. With bipolar leads reversal of phase was found corresponding to the tumor in 51 per cent, while low frequency potentials were found over the tumor in 73 per cent. The authors believe that the fact that they obtained better results than did Cobb in 1944 may be due to a difference in technical facilities, since Cobb only had a two channel recording device at his disposal.

Intracranial Teratomas.—According to Müller and Wohlfart the literature contains reports of 85 cases of intracranial teratomas and teratoids. The authors report 8 additional cases. Of these tumors, 5 were situated in the region of the pineal gland, 1 in the third ventricle, 1 in a suprasellar location and 1 in the cerebellum. The course was acute and rapidly progressive in every case. The patients had the symptoms from some weeks up to eight months prior to entry. In every case papilledema and other signs of increased intracranial pressure were present. The local symptoms were primarily vertical conjugated ocular paralysis and widened pupils not reacting to light. The pineal teratomas and teratoids occurred in a girl aged 7 years, in 1 boy aged 8 years, 1 aged 15 and in 2 youths aged 17. Teratomas and teratoids of the pineal gland as described in the literature have mainly occurred in young males. On histologic examination the rapid progression of the tumor could be explained as due to either malignant degeneration of part of the tumor or abundance of embryonic tissue. Oligodendroglioma can apparently develop from intracranial teratomas or teratoids. The authors suggest that cholesteatomas are related to teratomas.

*Constricting Chronic Pericarditis. Recovery After Partial Pericardiectomy in Case. A. Paulino Jr. and F. Arduino.—p. 205.

Constricting Chronic Pericarditis.—Paulino and Arduino report a case of chronic constrictive pericarditis treated by partial pericardiectomy. The disappearance of the ascites and venous congestion and improvement of the roentgenologic, kymographic, electrocardiographic and capillaroscopic changes were such as to warrant considering the patient cured clinically. At present, six months after the operation, the patient has resumed work.

*Direct Serologic Demonstration of Heterozygotia in Blood Groups A and B: Preliminary Report. P. Dahr.—p. 791.

Heterozygotia in Blood Groups A and B.—According to Wahr, the immediate determination of the hereditary character of the blood groups of persons whose blood is classified in the A and B groups by means of serologic examination is of great practical importance for the clarification of disputed descent in cases of affiliation. Results of previous experiments suggested that in heterozygotes (in AO persons and in BO persons) the direct serologic determination of the O property originating from the O anlage may be possible by means of agglutination examination with anti-O serums. Since any anti-O animal serum may contain other unknown antibodies, the examination of blood samples of known genotype by means of a hypothetic group-specific anti-O agglutinin may be performed only with a purified anti-O solution. Samples of bovine, equine or swine blood may be used for the production of anti-O serums, but only anti-O serum which retains a pronounced anti-O effect even on repeated saturation with A_2B blood will be useful. A method for the preparation of a purified solution of an anti-O serum of this type is described. A_1 and B blood corpuscles of known genotype were examined with the purified agglutinin solution and O, respectively. AB blood corpuscles (A_1B or A_2B, i. e., blood without O anlage) were always carried with as positive and negative controls. The bottle containing the anti-O serum broke before the experiments were terminated, and consequently the results may be considered only as preliminary. All O blood samples (genotype OO) which were used as positive controls gave positive reactions; all AB blood samples (A_1B and A_2B) without O anlage, serving as negative controls, gave negative reactions; all B blood samples of genotype BO gave positive reactions; all A_2 blood samples of genotype A_2O gave positive reactions. A_1 blood samples of genotype A_1O gave partly positive and partly negative reactions. A definite diagnosis of heterozygotia can be made only in case of a positive reaction with the group-specific anti-O, while with a negative reaction it remains an open question whether there is heterozygotia or homozygotia.

*Epidemic of Typhoid in Netherlands Troop After Arrival in Tropics. D. K. Wielenga and G. Bras.—p. 3474.

Case of Filariasis Bancrofti. P. Kooy.—p. 3481.

Typhoid in Troops After Arrival in the Tropics.—Wielenga and Bras describe an epidemic of typhoid which broke out among troops after their arrival in Java. A total of 80 cases occurred, of which 12 terminated in death. Postmortem examinations were made in 10 instances. Death was often caused by toxemia in the early stage of the disease. Hemorrhages were seen twice; in 1 patient a perforation developed at the hepatic flexure. The clinical picture was sometimes confusing because diarrhea of a dysenteric character existed, although neither dysentery bacilli nor Entameba histolytica were ever found. However, the possibility of a secondary infection was considered, and sulfaguanidine was administered in all cases of diarrhea with favorable results. To counteract the effect of toxins, transfusions of convalescent blood were given. A patient cannot be declared free from bacteria unless bile from the gallbladder has been examined and has proved sterile. Three bile carriers were successfully treated by duodenal intubation with magnesium sulfate solution; four urinary carriers were treated either with mandelic acid or by rendering the urine alternately alkaline and acid. The author stresses that prophylaxis against typhoid should be done with vaccines prepared from strains occurring in the locality to be visited.

*Gastric Ulcer: II. Pathologic Histology of Chronic Gastric Ulcer in Man. H. Betz.—p. 3.

Voluntary Apnea Time of Healthy Subject in Various Experimental Conditions. M. J. André and V. Boxus.—p. 42.

*Variations in Density of Arterial Blood and Its Hemaglobin Content in Course of Water Diuresis in Man. P. Govaerts and A. Verniory.—p. 78.

Contribution to Immunobiologic Study of Animal Fats. R. Derom.—p. 90.

Histologic Study of Chronic Gastric Ulcer.—Betz subjected to microscopic study specimens taken from the area of chronic gastric ulcers either in the course of resection or necropsy. He found fibrinoid necrosis in the intima of the arteries and in the connective tissue, often at a distance from the ulcer. Small hemorrhagic foci and edematous areas are often found near the ulcer. The occasional detection of signs of repair of the mucosa near the ulceration suggests that not all erosions become chronic. The intima of the arteries near the subserous tissue shows proliferation with differentiation of new muscular and elastic fibers. In over 38 per cent of the patients with chronic ulceration of the gastrointestinal tract who came to necropsy there existed disturbances in the general or portal circulation, which may have had repercussions on the gastric circulation. On the basis of these observations the author believes that neither emboli nor arteriosclerosis play a role in the pathogenesis of ulcer. Arterial occlusion is a consequence of local circulatory disturbances and not of arterial inflammation. It is not the cause of the ulceration. An allergic origin of the ulcer is possible but cannot be demonstrated by microscopic methods alone. If this hypothesis is correct, the circulatory disturbances would play their part only in the localization of the allergic reaction.

Changes in Arterial Blood During Water Diuresis.—Govaerts and Verniory studied the density of whole arterial blood and of its plasma in 30 persons by means of the Lindström-Lang technic. The hemoglobin content of the same specimens was determined with the Pulfrich photometer. About one hour after the ingestion of 1 liter of water, the density of blood decreases about 2.5 per cent, that of plasma 3.5 per cent. The hemoglobin content decreases by about the same percentage as does the density of the whole blood (an average of 2.73 per cent). If one wishes to express the dilution of blood in terms of increase in volume only hypotheses are possible. The first idea which comes to mind is that if the blood is diluted by water without losing or gaining protein or red cells, then 100 cc. of arterial blood should contain 2.61 cc. of excess water, distributed one fourth in the red cells and three fourths in the plasma. But although this concept is in perfect agreement with the observed changes, to prove it by direct observation would, for instance, entail demonstrating that the volume of the erythrocytes increased by 1.39 per cent. It is hardly possible to measure such a change by available methods. Other hypotheses might be suggested concerning the mechanism of blood dilution. One might assume that the fluid entering the blood is not pure water but a solution of salts and proteins, or one might postulate a removal of red cells from the blood after ingestion of water. Such hypotheses are not incompatible with the experimental results. However, they seem to be less probable than the first one and are not easier to prove by direct observation.

Book Notices

The Dispensatory of the United States of America. By Arthur Osol, Ph.G., M.S., Ph.D., Professor of Chemistry and Director of the Department of Chemistry, Philadelphia College of Pharmacy and Science, Philadelphia, George E. Farrar, Jr., M.D., F.A.C.P., Associate Professor of Medicine, School of Medicine, Temple University, Philadelphia, and others. Advisory Editor: Horatio C. Wood, Jr., M.D., Ph.M., Professor of Pharmacology, Philadelphia College of Pharmacy and Science, Philadelphia. Based on the Thirteenth Revision of the United States Pharmacopœia, the National Formulary, Eighth Edition, and the British Pharmacopœia 1932 and its Addenda. Twenty-Fourth edition. Cloth. Price, $16.50. Pp. 1928. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1947.

The Dispensatory of the United States of America is well known. Now in its twenty-fourth edition, U. S. D., as it is popularly known, provides a unique comprehensive review of the drugs recognized by the United States Pharmacopeia, the Pharmacopeia of Great Britian and the National Formulary, and of drugs that are not official in these books. It also offers information on general tests, processes, reagents and solutions, veterinary uses and doses of drugs, various tables that are found in the United States Pharmacopeia and National Formulary and other pertinent information. The first edition appeared one hundred and fifteen years ago and probably has been used more by the pharmacist than the physician. However, even though some may disagree with some of the statements of possible uses, the book has so much value that it can provide a real help to the medical practitioner as well as the teacher. Individual monographs are arranged alphabetically and provide information on official titles, synonyms and abbreviations, official definitions, unofficial synonyms, foreign language titles, trade names and trademarks, source of manufacturing process and its history, official descriptions including tests, assay methods, constituents, adulterants, therapeutic uses, toxicology, dosage, storage directions and official preparations. The format is agreeable for the average reader, and the style of writing and manner of treatment should be generally acceptable. The book should find its way into the libraries of those who insist on having adequate sources of references.

A Century of Service, Rochester General Hospital, 1847-1947. Written for the Hospital in Celebration of its One Hundredth Anniversary by Virginia Jeffrey Smith, Together with Chapters on the Medical Staff by Charles R. Witherspoon, M.D., Stearns S. Bullen, M.D., and William A. MacVay, M.D. Boards and Fabrikoid. Pp. 227, with illustrations. Rochester, N. Y., 1947.

Beautifully printed and designed for public interest as well as for reference as a historical document is this review of a great American institution, the Rochester General Hospital. It came into existence following the depression of 1837 and it grew out of a female charitable society. It added a school of nursing and the other functions that hospitals have added in modern times. The story is told simply and directly with many illustrations, and the book might well serve as a model for other volumes dealing with similar institutions. Since the hospital was always conducted efficiently and economically, the record of its growth and development is also a guide to modern hospital administration.

Cornell Conferences on Therapy. Volume Two. Edited by Harry Cold, M.D., Managing Editor, and others. Cloth. Price, $3.75. Pp. 354. The Macmillan Co., 60 Fifth Ave., New York 11, 1947.

By now Cornell Conferences on Therapy have become familiar to students and teachers. The series was begun in 1937 and for several years was published in The Journal of the American Medical Association. Volume I was so successful that a second printing was necessary within a few months after its publication. Volume II, which comprises a series of sixteen conferences, should be equally successful as it will be of interest to the intern, resident, practitioner, and teacher. There were almost forty participants in the conferences, which include discussions of the use of placebos in therapy, treatment of poliomyelitis, treatment of meningitis, treatment of syphilis, treatment of rheumatic fever, oral penicillin, choice of sympathomimetic amines, management of gallbladder disease, principles of treatment of edema and dehydration, uses and abuses of quinidine, treatment of coronary artery disease, treatment of some tropical diseases, surgical treatment of hypertension and the evaluation of local antisepsis. Those who have participated in these conferences are well known in the fields in which they work, and authenticity is given to this book by the association of their names.

Essentials of Pharmacology. By Frances K. Oldham, M.Sc., Ph.D., Research Associate in Pharmacology, the University of Chicago, Chicago, F. E. Kelsey, Ph.D., Associate Professor of Pharmacology, the University of Chicago, and E. M. K. Geiling, Ph.D., M.D., Frank P. Hixon, Distinguished Service Professor and Chairman of the Department of Pharmacology, the University of Chicago. Fabrikoid. Price, $5. Pp. 440, with illustrations. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1947.

This is intended to serve as an introductory textbook on pharmacology. It does not contain detailed information for the advanced student, and the authors have wisely omitted lengthy discussions of articles seldom used in modern therapy. The book is up to date and conforms to the products listed in the latest editions of the official compendiums, N. N. R. and other recognized volumes. Included in the discussions are the functional drugs and chemotherapeutic agents, but one of the most interesting sections of the book is related to general principles, in which are statements on historical development of pharmacology, general principles of pharmacology, control and dispensing of drugs and administration of drugs. Brevity is an outstanding feature of the book, and yet this does not lessen its usefulness.

Practical Difficulties in Pharmaceutical Preparations. Collected from the Notes Left by Late Mr. Avadhut K. Pradhan, B.Pharm., Ph.C. Compiled by Dr. K. N. Pradhan, L.M. & S. Avadhut Memorial Series No. 1. Paper. Price, 2 rupees. Pp. 12. Published by R. T. Deshmukh, at Saraswati Press, Nagpur, for Late Avadhut Memorial Trust, Avadhut Bhuvan, Nagpur, 1947.

This is a brief collection of notes left by a young man, a pharmacist, who was beaten and killed, and whose body disappeared in Calcutta, India.

Formulary, University Hospital, Ann Arbor, Mich. Second edition. Cloth. Price, $3.75. Pp. 422, with illustrations. University of Michigan, University Hospital, Ann Arbor, 1947.

The development of hospital formularies has assumed an important place in hospital life. Some have been so well received that the reception has extended beyond the walls of the hospitals for which they were originally intended. This formulary, prepared by the University Hospital, Ann Arbor, Mich., is such a publication. The first edition appeared in 1946, the second in August 1947. So many developments have occurred that it was necessary to add new sections, including discussions on amino acids, the newer analgesics, antihistaminics and other drugs that have now gained either general recognition or are being widely used for clinical research. Each drug is identified as to whether it is U. S. P., N. F. or N. N. R., although some appear that are not in any of these books. In addition to the descriptions there are statements of dosage. Wisely, the writers of the volume have seen fit to omit detailed descriptions of actions and uses. This is a creditable attempt to provide a useful formulary for the hospital staff.

Le pouvoir antiprotéolytique du sérum sanguin chez la femme. Par Roger Le Breton, Docteur en médecine. Paper. Pp. 103, with 4 illustrations. Imprimerie M. Declume, Lons-Le-Saunier, 1946.

The author has developed a new, simple technic for the determination of the antiproteolytic power of blood serum. Experimental conditions such as the quality of the materials used and the temperature and duration of the reaction were strictly controlled. He measured antiproteolytic power in terms of the inhibitory action of 1 cc. of serum, as determined by the percentage of fibrin remaining unchanged during digestion with a proteolytic ferment. Proteolytic power was measured by the percentage increase of the fibrin broken down under the same conditions.

The method enabled the author to gather evidence in the female of a hitherto unknown proteolytic power of certain blood serums, but most of his data concern the antiproteolytic power of the blood serum in various obstetric and gynecologic conditions. Four hundred and sixteen observations were carried out in 314 female patients, of whom 168 were pregnant. More often than not, only one determination was done in each patient. He found a diminution of the antiproteolytic power in patients showing (1) death of the fetus in utero, (2) habitual abortion, (3) the menopause. An increase was found in (1) pregnancy, (2) the immediate period following castration, (3) gynecologic infections and (4) during autohemotherapy combined with sulfarsphenamine in patients treated successfully for habitual abortion. There was a transition from antiproteolytic to proteolytic power in metrorrhagia and occasionally in the menopause. Although he found an analogy between the curves of evolution of antiproteolytic power and that of folliculinemia in the course of gestation, this was not the case during the menstrual cycle. The increase in antiproteolytic power provoked by infections points to a defense reaction, not necessarily an estrogenic mechanism. Because of this increase, it is imperative that every patient have a physical examination and white blood cell count in order to rule out an infection.

The author claims that the determination of the antiproteolytic power of the blood serum offers a diagnostic procedure in pregnancy and a method of control of the treatment of habitual abortion by autohemotherapy combined with sulfarsphenamine.

Biological Actions of Sex Hormones. By Harold Burrows, C.B.E., Ph.D., F.R.C.S. Cloth. Price, $8.50; 42s. Pp. 514, with 7 illustrations. New York: The Macmillan Company; London: Cambridge University Press, 1945.

This is a well coordinated summary of developments in our knowledge of the sex hormones derived from the study of the pituitary, gonads and adrenals in animals. It shows an appreciation of the varying factors which must be taken into account when discussing any reaction. For example, in Part I, on the subject of gonadotropins, there is a chapter devoted to factors which influence the gonadotropic activity of the pituitary, another on factors which influence the reaction of the gonads to gonadotropins and another on factors which affect the cytologic structure and weight of the anterior lobe of the pituitary. The section on androgens has a chapter dealing with the action of these hormones on the reproductive system before complete differentiation and another chapter on their action after complete differentiation. The section on estrogens is treated in the same manner. The author states that his leading motive is the ultimate possibility of applying the experience gained from the laboratory for the benefit of man. In general, he wisely refrains from a direct attempt to do so in this book, perhaps realizing that conclusions based on animal experiments cannot always be applied to man without considerable modification. An appendix gives synonyms for the biologic products used, and a glossary explains some of the technical terms. There is both an author and a subject index.

The Premature Baby. By V. Mary Crosse, M.D., D.P.H., M.M.S.A., Chief Obstetric Officer in Charge of City of Birmingham Maternity Homes and Premature Baby Unit, Birmingham, England. With foreword by Leonard G. Parsons, M.D., F.R.C.P., F.R.C.O.G., Professor of Children's Diseases, University of Birmingham. [Reprint] Fabrikoid. Price, $3. Pp. 156, with 14 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1946.

Dr. Mary Crosse, the author, is chief obstetric health officer in charge of maternity homes and the premature baby unit of the city of Birmingham, England. Fourteen years ago she commenced an attack directed toward the reduction of mortality among premature babies. Her work was so encouraging that English physicians, who watched her, often wished that she would describe her methods, so that others might profit by them and follow her example. This book is the result. According to the English pediatrician Dr. Leonard G. Parsons, her experience and results in this field have been unrivalled in that country. According to him the book is unique in British literature.

The book is divided into eight chapters, an appendix and an index. The chapters deal with characteristics of premature infants, general scheme of management and care, institutional care, home care, clothing, methods of feeding, complications that occur in premature babies and various tables and statistics relating to the premature baby in England. There are fourteen illustrations, most of which are photographs illustrating various technics, i. e., weighing, bathing, feeding, administration of oxygen, ultraviolet radiation and the like.

This book is, according to American standards, more in the nature of a compend or outline and is generalized more than detailed. A special feature is the teaching of simple methods; methods that any English midwife could employ when called on to nurse a premature baby in its own home. English physicians visiting this country have stated that Dr. Crosse and her book have done much to acquaint the English physician in the care of premature infants and to bring about a resulting reduction of mortality.

However, the book would not be suitable for teaching of American physicians, because books and articles available to the American physician are more detailed in the employment of technical procedures used in this country. For example, Dr. Crosse pictures a heated uncovered transport basket, whereas in larger cities here an enclosed transportable incubator is frequently used; oxygen is administered by face mask rather than by the tent, hood or enclosed incubator more commonly used here. Intravenous therapy is not stressed because of the lack of trained personnel.

This is distinctly an English book for the British general practitioner and as such has served a useful purpose in the British Isles.

Office Endocrinology. By Robert B. Greenblatt, B.A., M.D., C.M., Professor of Endocrinology, University of Georgia School of Medicine, Augusta, Georgia. With a foreword by G. Lombard Kelly, M.D., Dean, University of Georgia School of Medicine, Augusta. Third edition. Cloth. Price, $4.75. Pp. 303, with illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1947.

This book claims to give the practicing physician the latest practical, reliable facts about endocrinology, simply and definitely; yet almost all of the volume is devoted to "female endocrinology." There is a brief section on "male endocrinology." Another brief section on "hormonology" and a five page introduction on "regulatory mechanisms" cover the rest of the endocrine system. The section on hormonology merely describes the actions of the estrogens, progesterone, androgens and the adrenal cortical, thyroid and pituitary hormones. Thus, there are no clinical data on any endocrine glands other than the gonads. The pancreas and parathyroids are not mentioned in the section on hormonology. "Female endocrinology," which occupies most of the book, is a condensed outline containing many practical points in diagnosis and treatment. Some of the recommendations seem a little optimistic. Hormone nomenclature is well covered in the section on hormonology.

Solutions and Dosage. By Sara Jamison, R.N. Cloth. Price, $2.50. Pp. 295, with 62 illustrations. McGraw-Hill Book Co., Inc., 330 W. 42nd St., New York 18, 1947.

An understanding of simple arithmetic, through "percentage" and "ratio and proportion," is essential to the accurate preparation and administration of drugs. This textbook provides a clear presentation of simple mathematical relations, explained in terms of both the apothecary and metric systems of units. It contains chapters on arithmetic review, on the preparation of solutions and on dosage, with many exercises and experiments designed to develop facility in accurate calculation. The problems deal with drugs used in modern therapy. This book should prove useful to student nurses, pharmacy students and physicians who wish to review simple arithmetic.

Diseases of the Nervous System Described for Practitioners and Students. By F. M. R. Walshe, M.D., D.Sc., F.R.C.P., Physician in Charge of the Neurological Department, University College Hospital, London. Fifth edition. Cloth. Price, $1.50. Pp. 351, with 59 illustrations. Williams & Wilkins Co., Mount Royal & Guilford Aves., Baltimore 2, 1947.

This is a most practical and useful book. The author writes from a standpoint of physiology and anatomy and therefore does not force the student or practitioner to memorize individual symptoms of each nervous disease. This format and this method of describing neurologic diseases are well adapted to a book of this type. The twenty-nine chapters are divided into two parts. Part I takes up the general principles of neurologic diagnosis. Part II gives a descriptive account of the commoner diseases of the nervous system. This book is written for the student and the general practitioner, but it should be in the hands of all medical men—practitioners as well as specialists.

The Diagnosis and Treatment of Diarrheal Diseases. By William Z. Fradkin, A.B., M.D., Assistant Attending Gastroenterologist, Jewish Hospital of Brooklyn, N. Y. Cloth. Price, $6. Pp. 231, with 111 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1947.

This short manual covers thoroughly the diarrheal diseases from clinical, laboratory and public health aspects. In addition, the introductory chapters discuss related anatomy, physiology, bacteriology, pathology and diagnostic procedures and technics.

There is unquestionably a wealth of material in this manuscript, but the method of presentation leaves the reader wondering why so much space is wasted in description of simple laboratory procedures and methods of physical diagnosis and so little time spent in interpretation of results. By the same token, therapeutics is described in general terms. The practitioner who wishes to use this for reference will find complete lists of suggested treatments but little discussion of their indications.

This oversimplification on one hand and painful detail on the other suggests that the manual be recommended for study by medical students and young practitioners. It will not be found of great value by experienced gastroenterologists.

Dying, Apparent-Death and Resuscitation. By S. Jellinek, M.D., Professor of *Electropathology at the University of Vienna, Vienna.* Cloth. Price, $3.50. Pp. 263. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

The author of this book spent his lifetime collecting data and making notes on this subject. Some of the material is interesting, but a large part is irrelevant. The author calls "The practice of lifesaving today—a dismal medical wilderness." Knowledge of resuscitation should be a requirement for the practice of medicine. Dr. Jellinek attempted to formulate a program for resuscitation. He is professor of electropathology at the University of Vienna, where they have "a pathologic museum which is practically a department of life saving."

The first paragraph of the first chapter indicates the author's style and presentation: "It is in itself a strange contradiction that some learned doctors of strict integrity do not hesitate to pronounce categorically that there is in reality no such thing as 'apparent-death,' whilst others of no less esteem make testamentary depositions that the heart-incision shall be performed on them; but this contradiction reveals the darker side of the problem which has tormented mankind throughout the ages. Neither the attitude of the opponents of the 'apparent-death' theory nor that of its adherents can stand up to critical examination. The former unscrupulously disregard every argument and simply deny the existence of apparent-death and its concept, the latter believe in apparent-death but bring discredit on the idea. The opponents press their arbitrary dogmatism (in support of which they are unable to advance a single argument from the field of objective knowledge) to the point of saying that even babies born in a state of asphyxia should be regarded as dying or stillborn, forgetting in their ardor (not to call it fanaticism) that even the object of contention, i. e., the alleged seemingly-dead person, has the right to be heard and justly treated."

The second chapter, on "Fables and Facts," starts off with this sentence: "Myths, sagas and chronicles of all times show that those fundamental and inexorable phenomena of life, death and its shadow, apparent-death, have deeply troubled mankind throughout the ages."

The third chapter is on "Clinical Thanatology" and begins as follows: "Not only has life pulsating freshly in each one of us its own peculiar motif, its own rhythm; but the sonorous finale, death, has in each one of us its individual cadence."

There are 246 pages of material similar to the foregoing quotations. The book is a compilation of notes and observations largely of a metaphysical nature. This reviewer would not classify it as a textbook for students and practitioners of medicine.

The Medical Writings of Anonymus Londinensis. By W. H. S. Jones, Litt.D., F.B.A. Cloth. Price, $2.75. Pp. 168. Macmillan Co., 60 Fifth Ave., New York 11; Cambridge University Press, Bentley House, 200 Euston Road, London, N. W. 1, 1947.

This book is the author's translation of a Greek medical papyrus of the second century A. D., measuring 12 feet long, consisting of thirty-nine columns, each containing fifty to sixty lines about 3 inches long, with some mutilated and illegible parts. It is probably not a copy of an edition but is probably a copy by a young student of another copy, or rather a paraphrase of such by one and the same scribe—perhaps of lecture notes. No post-Aristotelian authority is mentioned, and it is probably of a Menonian origin.

After a short preface, followed by an introduction and "additional notes" and the bibliography, there follows the running text in Greek on the left side of the succeeding pages, with the corresponding English translation on the right sides of the pages.

The text begins with definitions of Greek words followed by the etiology of diseases, according to various authorities, and ends with the development of physiology after 300 B. C. (from Herophilus to Alexander Philalethes). The last section (on physiology) is quite the largest of the three. The book ends with a chapter on "The Nature of Greek Thought" and "The Nature of Greek Medicine," followed by one and one-half pages of an "Index of Notabilia."

This book is of little interest to the general practitioner of medicine. Even its arrangement is a bit disconcerting; except for the first four and one half pages of introduction, the "additional notes," chiefly of philologic interest to the Greek scholar, had better be put at the end of the text after the interested reader has discovered the detailed nature of the text. The translator's suggestion that the text is a paraphrased copy of lecture notes by a young student seems justified because of its repetitious parts and other "existing blemishes." Its physiologic section with its anatomic references is the most interesting to any student of the history of physiology. Of the latter it is stated that simple parts of man such as "brain, sinew, artery and vein are such because these can be cut up into like parts whereas compound parts such as legs, liver, head and lung are not homogeneous."

The original lecturer author was conversant with the fact that arteries contain blood and not breath (air). Of the foods ingested some may contain good and bad material on digestion; but the bad is excreted by the urine for the latter is "pungent and salt," which ends the physiology of the bladder; for even the sun, "being an intelligent ball of fire out of the sea, is nourished from the nutritious parts of the sea, taking in part what is fine, but leaving in the sea the more sluggish, the grosser and salt portion" (p. 117). On the basis of alleged facts, athletes are fed with warm loaves of bread and fresh meat because they are heavier than high meat and cooled loaves which, because they are light by nature, are less nutritious and have in cooling given off many emanations. Empirics oppose this view because they say "the addition of one thing to another does not necessarily make the latter heavier," for sometimes much addition makes the object lighter and sometimes the subtraction of a part of the object makes the object heavier; for a bladder filled with air is lighter than an empty bladder, or as when the soul leaves the body, the body becomes lighter (p. 131). Aside from the lack of suitable scales, the fallacy implied in the simple mathematical statement should have been apparent.

However, the didactic value in principle of these lecture notes lies in the fact that in the expositions of physiologic processes the authorities are cited for one view or the other. A discussion of diverse opinions with bibliography often is not presented even at this age by many so-called modern teachers of medical students. Here the ancient bibliography is present in the form of references to the views of Herophilus, Erasistratus, Plato, Hippocrates, Aristotle, Thrasymachus and so forth. To repeat: this book is of interest only to the medical historian and Greek philologist and not to the practitioner of medicine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VAGINAL SMEARS FOR DIAGNOSIS OF CANCER

To the Editor:—Please describe a simple office procedure for taking vaginal smears for the early detection of cancer of the uterus.

Rudolph Joseph, M.D., Freeport, N. Y.

ANSWER.—The technic for preparing vaginal smears, as described by G. N. Papanicolaou and H. F. Traut (Diagnosis of Uterine Cancer by the Vaginal Smear, New York: The Commonwealth Fund, 1943) is as follows:

"A slightly curved glass pipet, 6 inches (15 cm.) in length, 0.5 cm. in diameter with a rounded tip and a small opening, and equipped with a strong rubber bulb for producing suction is used. The patient is placed on an examining table in the lithotomy position. The labia are separated and the rubber bulb compressed. The glass pipet is introduced into the posterior fornix of the vagina. The pressure on the bulb is then released and the suction produced serves to aspirate vaginal fluid with its cellular content into the glass tube. While aspiration is in progress, the tip of the tube is moved from one side of the fornix to the other so that all parts are sampled. The pipet is then withdrawn, and the vaginal material is spread on the surface of a clean microscope slide with a sudden expulsive pressure on the bulb. Further spreading with the convex side of the pipet is advisable when the amount of fluid is abundant, as in cases where there is considerable bleeding or abundant mucus. Very thick smears are not well penetrated by the fixing fluids and cannot be uniformly stained.

"The slides are immediately plunged into a solution of equal parts of 95 per cent alcohol and ether. Drying of the smears should be carefully avoided as it results in the loss of the sharp outlines of the cells, and in a change in their staining reaction. The fixation does not require more than a few minutes, but smears may be kept in the alcohol-ether solution over a long period of time. It is recommended that the slides not be kept in the fixative for more than a week or two as the cells slowly tend to lose their normal staining reaction. If ether is not available, plain alcohol (95 per cent) can be used. For shipping slides, a square bottle 1¾ by 1¾ by 4½ inches (4.5 by 4.5 by 11.4 cm.) may be used. Such a bottle may hold as many as seven or eight slides. An ordinary paper clip attached to each or every other one of the slides prevents the smears from rubbing against one another.

"A few precautions should be observed in the procurement of material for the vaginal smear. The vaginal contents should not have been disturbed by any form of examination or treatment. Douching or bathing will, of course, dilute or completely wash away the cellular deposits for a period of several hours. If there is a considerable amount of fluid of either serosal or sanguineous character, dilution will occur, in which case it is wise to make several smears to obtain the representative cell constituents which are ordinarily seen in a single smear."

ADENOIDECTOMY

To the Editor:—A child aged 3½ years has enlarged tonsils without evidence of gross infection but has occasional attacks of sore throat. A pediatrician suggests removal of adenoids and states that tonsils may improve as a result of the adenoidectomy. Is such a procedure preferable to the customary tonsillectomy and adenoidectomy? At what age and in what season are such operations best performed? Is preoperative administration of vitamin K and penicillin indicated in these cases?

R. V. Brokaw, M.D., Trenton, N. J.

ANSWER.—Because of a natural tendency to routinize procedures, both tonsils and adenoids are usually removed at the same time. There must be numerous occasions, however, when either the tonsils or adenoids alone should be removed.

In each case the determining factor should be the past history of the patient and the observations at previous examinations and at the time of operation. If the indication for operative removal of the tonsils is absent then they should not be removed.

This statement would be academic, however, if it did not take into account a number of facts. Assume that the child appears to need adenoidectomy only. In a year or so he will be of school age and will be in frequent contact with many other children at a time when they are all most susceptible to infections of the upper part of the respiratory tract. Neither the parents nor the physician would shortly like to be confronted with the need for another operation with its physical risks and psychic trauma.

The problem would be simpler if the child had never had trouble with his tonsils; it is more difficult if the past history is that of a few mild attacks. The next attack may or may not be soon and severe.

In the last analysis, then, at the time of adenoidectomy one would remove the tonsils described if it is believed that they have already or will shortly cause more disturbance. The history of the patient and the skill and judgment of the physician will be more helpful toward a solution than the present appearance of the tonsils.

Set age or optimum time for operations of this type is not established. They are to be carried out when sufficient indication for operation is present.

Borderline cases may be postponed and observed, and other measures such as radiation therapy considered, until operative removal becomes clearly the method of choice. No reason exists for believing that adenoidectomy alone will improve diseased tonsils.

This operation should not be done in the presence of a poliomyelitis epidemic or at the height of an ordinary seasonal rise in poliomyelitis.

In children who are allergic or who come from allergic families an operation at the height of the pollen seasons is not desirable.

A number of competent observers believe that neither vitamin K nor penicillin offer additional protection.

THROMBOPHLEBITIC ULCERATION

To the Editor:—I have a female patient, aged 42, who has four children. Questionable evidence of phlebitis occurred after the last delivery, which was eleven years ago. Seven years ago the patient had a pelvic operation, after which there developed deep phlebitis on the left side. Extensive eczema and ulceration of the lower part of the leg also developed. A high saphenous ligation and two flap operations have been performed with little, if any, improvement of her condition. With the history of phlebitis I doubt if satisfactory result will be obtained from attacking the superficial saphenous condition. She still has varicose veins, but undoubtedly these are due to a compensatory mechanism. What is the status of lumbar sympathectomy and the excision and grafting procedure? What is suggested in treatment of this condition?

John S. Reed, M.D., Kingsport, Tenn.

ANSWER.—The treatment of chronic recurrent, thrombophlebitic ulceration is admittedly difficult. Since the chronic venous stasis is brought about mostly through a reflux in the deep venous system, ligation of the saphenous vein at the groin is not apt to be of much help. However, this factor has to be studied in each case. Certainly injection into the saphenous collateral vessels in the presence of a thrombophlebitic induration and eczema will only result in more edema and lymphstasis. Ligation of the superficial femoral vein, if its patency can be ascertained, is more logical, since the recanalized, thickened valveless deep venous system is responsible for much of the venous stasis in the erect position. The selection of the proper type of patient for this operation requires a great deal of experience; the operation may do more harm than good if deep venous pressure is increased by the procedure.

Lumbar sympathectomy is useful but only in those patients who exhibit increased sweating, decreased pulsation and decreased skin temperatures in the affected extremity.

Wide excision of the ulceration, down to or including the deep fascia, followed by a split-thickness skin graft taken with a dermatome is the method of choice in most instances. This operation not only removes the indurated, inflamed tissue around the ulcer but interrupts the incompetent perforator veins and excises the strangled and inflamed peripheral nerve supply. It must be followed by many months' use of snug elastic support with glycerin-gelatin casts and later use of elastic hose.

RHEUMATIC HEART DISEASE

To the Editor:—A boy aged 5 years, who lived in St. Louis and who had a known functional heart murmur contracted a streptococcic tonsillitis and pharyngitis. Several days later mild scarlet fever developed. A mild rheumatic heart disease resulted. The child is convalescing from the rheumatic heart disease, and apparently there will be no residual cardiac involvement. He is now in Arizona recuperating. The problem arises as to the advisability of returning this boy to St. Louis during the winter months. Should he remain in central Arizona where the climate is warm and dry and where there is supposedly less tendency for rheumatic fever to occur?

M.D., Arizona.

ANSWER.—Clinical experience has shown that in mild and dry climates there is in general less streptococcic respiratory infection than in the colder, wet regions of the northern temperate zone. The chief hazard to a patient recovering from recent rheumatic fever is a recurrence or recrudescence of his disease, and streptococcic infection is the commonest precipitating factor. Hence, the patient would be less apt to have a recurrence in a climate such as Arizona than in St. Louis during the winter months.

TRAUMATIC EPILEPSY

To the Editor:—A patient aged 20 had a fractured skull, grossly bloody spinal fluid and a Babinski reaction on the right side. One and one-half years after the injury to the skull, the patient commenced to have seizures that started with an outcry and spasm of the jaw muscles, first on the left side, followed by a short period of unconsciousness and clonic movements of both legs. Neurologic examination is now repeatedly negative. The electroencephalogram showed, "steady 10 per second; no focus; no seizure discharges; slight build-up with overventilation. A minor attack occurring during the record showed no change." In the light of this evidence can I make the following conclusions? 1. The history of a Babinski reaction on the right side and the start of the seizures on the left side of the face suggests a focus, very probably of traumatic origin. 2. The essentially normal electroencephalogram does not rule out focal epilepsy, so-called, but a positive tracing would be fairly conclusive evidence of the existence of focal epilepsy.

M.D., New Hampshire.

Answer.—The site of the fracture of the skull is not stated. The other evidence is contradictory, but probably the left-sided muscular spasm that initiates seizures is of more significance than the former right-sided Babinski reflex. The diagnosis of focal grand mal epilepsy is made by the description of the seizures. The normal electroencephalographic tracing does not alter this diagnosis, although the failure to record a seizure discharge during a seizure is peculiar. A record made during sleep should be more revealing. The possibility of a subdural hematoma is to be considered.

DILUTE HYDROCHLORIC ACID

To the Editor:—What is the rational of the use of dilute hydrochloric acid and a low salt diet in hypertension?

M.D., New York.

Answer.—Theoretically, dilute hydrochloric acid in combination with a low salt intake should tend to lower the sodium content of the body even more effectively than a low salt diet alone. The idea of low salt therapy for hypertensive disease is not new. Earliest studies along these lines were by the French (Achard, C., and Leoper, M.: *Compt. rend. Soc. de biol.* **53:**345, 1901; Widal and Lemierre: *Bull. et mém. Soc. méd. d. hôp. de Paris* **20:**785, 1903). Experimental studies with rats (Grollman, A., and others: *J. A. M. A.* **129:**533 [Oct. 20] 1945) indicate that radical reduction in sodium content reduces the blood pressure in experimentally induced renal hypertension. The rice diet advocated by Kempner (Kempner, W.: *North Carolina M. J.* **5:**125 [April] 1945; *ibid.* **5:**273 [July] 1944) is based on the concept that it supplies the minimum amount of sodium and is extremely low in protein, thus sparing the kidneys.

However, the clinical value of severe sodium restriction and depletion of sodium reserve in hypertensive disease is by no means fully demonstrated. Clinical improvement claimed by those advocating this method of therapy has not been confirmed with sufficiently extensive and well controlled studies elsewhere. For years the pendulum has swung back and forth: waves of enthusiasm for severe salt restriction have been followed by waves of skepticism and demonstration that such an unpalatable diet does not accomplish enough to warrant insistence on its continuance. Experimental renal hypertension finds its counterpart in only a relatively small percentage of cases of hypertensive disease in human beings. Hypertension is due to many causes; the etiologic factors are seldom identical in different patients. Anxiety plays an important role in many instances. It is notable that only those patients who are extremely apprehensive regarding their hypertension will follow the strict dietary regimen for any length of time and that such persons are particularly open to the psychogenic effects of faith and reassurance.

MENOPAUSE

To the Editor:—Please advise me regarding estrogen administration, which was discussed in *The Journal*, Nov. 8, 1947, page 680. A patient had an early menopause at 35 years of age: she has not menstruated for ten years (aged now 46). She still has hot feelings and flushes, and her skin is hot at night in bed. She gets relief with 5,000 units of theelin twice a month or every ten days but has been receiving it for ten years. Her mother aged 62, died three years ago with metastases to uterus and ovary following removal of a cancer of the breast fifteen years previously. Should this patient receive any more theelin? She is a high strung, emotional woman.

Frederick G. Wandall, M.D., Clayton, N. J.

Answer.—In treating menopausal symptoms, patients who have a personal or familial history of cancer of the accessory sex organs should not receive estrogenic therapy. This patient is apparently emotionally unstable, and perhaps there has been considerable psychic trauma due to the fact that her mother died from a dreaded cancer. Sedation and reassurance may be of value in the relief of some of her symptoms. The use of androgens has been recommended as benefiting patients in whom estrogens are contraindicated.

RIGHT-SIDED HEART FAILURE

To the Editor:—Please give an opinion on treatment of acute right-sided heart failure. I meet this condition occasionally in older patients with chronic emphysema associated with chronic bronchitis and/or bronchiectasis and in younger patients with mitral stenosis.

The former may have attacks of pain in the abdomen which mimic closely an acute condition of the upper part of the abdomen such as gallstones, or pain may occur at the lower end of the sternum, in which case it is apt to be misdiagnosed as a coronary attack. In the latter group pain is more often apt to be entirely abdominal. Rigidity of the upper part of the right rectus muscle may occur. The liver is sometimes excessively enlarged, either temporarily or permanently, or it may not be palpable. The veins of the neck are frequently distended.

My patients are usually taking digitalis and may be fully digitalized at the time of the attack. During the attack the pulse becomes of poor quality and the extremities become cold. Should such a patient be bled, even if he appears to be in shocklike state? Is acute right-sided heart failure always an indication for bleeding?

The method of treatment is partly the treatment of medical shock; e. g., treatment of "forward" heart failure in acute coronary thrombosis, in which the patient may die in a few hours. A better example is the circulatory failure of diphtheria. At a recent cardiac conference one cardiologist expressed the opinion that such a child should have been depleted with mercurial diuretics, although the child received 1,000 cc. of blood in divided doses.

Patients with mitral stenosis whom I have seen in acute attacks have had few or no basal chest rales.

What treatment is advised?

Samuel L. Immerman, M.D., Philadelphia.

Answer.—Engorgement of the liver with resulting pain and tenderness in the right upper quadrant is an early sign of failure of the right ventricle usually secondary to left ventricular failure with its attendant dyspnea or orthopnea but also found in cases of mitral stenosis, cor pulmonale, myocardial disease and strain acting diffusely on the whole heart, as in acute rheumatic pancarditis and acute tamponade of the heart by pericardial effusion. In the case of persistently recurrent or chronic hepatic congestion and enlargement one finds decreasing pain and tenderness in the right upper quadrant, although the liver may be enlarged to great dimensions.

The most important treatment of acute vascular congestion of the liver is combined therapy with digitalis, mercurial diuretics and low sodium intake. The use of venesection, or preferably blood pressure cuffs to the far extremities, in acute emergency is seldom needed if one seeks to obviate the possibilities of such a condition by prophylactic treatment. This problem in the case of acute right-sided or total cardiac failure is much less serious or common than that of acute pulmonary edema associated with failure of the left ventricle, but a similar dilemma exists as to the relative importance of venous congestion and a state of shock. Venesection would seem to be much less desirable than the cautious use of blood pressure cuffs; and conceivably even the introduction of fluid, preferably blood, in small amounts might help if such a rare emergency should supervene.

BILATERAL CONGENITAL CATARACTS

To the Editor:—Three weeks ago a boy with bilateral congenital cataracts was born. History of German measles during pregnancy is absent and no familial history of cataract occurs. Both parents are apparently in good health. Please discuss newest methods of treatment.

M.D., New York.

Answer.—There may be other noxious agents than German measles which produce bilateral congenital cataract, but as yet only heredity has been confirmed as a cause. Presence or absence of other congenital anomalies in the eye or eyes is naturally of great importance in prognosis. Many infants are operated on during the first year but most authorities prefer to wait until the child is 2 years of age. Secure the best possible result in one eye before the second is touched. Several operations may be needed. Select a competent ophthalmologist, one who has done a good many such operations in babies. The prognosis for vision is good.

SMALLPOX

To the Editor:—I have just treated a patient with smallpox by giving 50,000 units of penicillin intramuscularly every three hours. Penicillin did not seem to affect the eruption as it was taking place, but it did appear to have a profound effect in drying the eruptions and hastening the scaling stage. What are the reports of others using penicillin against smallpox?

Clifton F. West, M.D., Kinston, N. C.

Answer.—A report of an outbreak of smallpox in American military personnel in Japan by Agerty (*New England J. Med.* **237:**305 [Aug. 28] 1947) relates that penicillin was used in amounts varying from 160,000 to 240,000 units a day. No obvious effect on the course of the disease followed penicillin therapy. If the eruption of the skin is secondarily infected with hemolytic streptococci or Staphylococcus aureus, penicillin might control the infection. In brief, penicillin may be useful if a secondary infection of the cutaneous lesions is present but has no influence on the course of smallpox itself.

TINNITUS

To the Editor:—A patient aged 48 has had unilateral hearing since birth. Subsequent to a surgical procedure tinnitus developed and has persisted now for fourteen months. The hearing loss is 15 decibels. Is the nature of the pathologic process known? Is there any worth while form of treatment? Is there a chance that the tinnitus may stop? What is the prognosis for further loss of hearing?

M.D., Connecticut.

ANSWER.—A diagnosis of the type or cause of the hearing loss cannot be made without a complete otologic study, including inspection of tympanic membranes and eustachian tubes and audiometric and tuning fork tests. Treatment of tinnitus is exceedingly unsatisfactory. Nothing can be done unless the tinnitus is due to reversible pathologic changes in the ear, such as occlusion of the eustachian tube.

INNERVATION TRAPEZII

To the Editor:—While sitting behind a patient, if one examines his upper trapezii by pinching or squeezing them between the thumb and index finger of each hand one often observes: (1) a sort of reflex contraction of superficial tissues toward the "pinched" side, so that the nuchal septum is deviated toward that side; (2) the formation of a lump in the superficial tissues over the area examined, sometimes accompanied by crepitation—a sort of contraction of the subcutaneous tissues perpendicular to the muscle and directly under one's fingers: Have these been described before? Please explain and give references.

S. Arana-Soto, M.D., San Juan, Puerto Rico.

ANSWER.—The innervation of the trapezii muscles has been studied in detail in various animals, including monkeys, by K. B. Corbin and Frank Harrison (Proprioceptive Components of Cranial Nerves: The Spinal Accessory Nerve, *J. Comp. Neurol.* 69:315, 1938; Sensory Innervation of Spinal Accessory and Tongue Musculature in Rhesus Monkey, *Brain* 62:191, 1939). They found that the ventral rami of the second, third and fourth cervical nerves contribute sensory fibers to the trapezii muscles, a few from the second, more from the third and all of those from the fourth cervical. These muscles are supplied with proprioceptive fibers whose cells are situated in the dorsal root ganglions. The fibers pass peripherally over the respective cervical ventral rami, finally anastomosing with the accessory nerves before entering the muscles. The authors expressed the belief that it is reasonable to conclude that a similar condition obtains in man.

The phenomena you have observed probably are due to these sensory nerves reflexly stimulating the muscles. Francis Marion Pottenger ("Symptoms of Visceral Disease," ed. 6, St. Louis, C. V. Mosby Company, 1944) discusses various reflexes and trophic changes in the trapezii region, as well as those of the other accessory muscles set in operation by pulmonary diseases and conditions through the upper cervical nerves. He states that the visceromotor, viscerosensory and viscerotrophic reflexes which arise from stimuli originating in the lungs seem to manifest themselves throughout most of the cervical segments but are more pronounced in the third and fourth. They appear as motor and sensory changes in the tissues supplied by the cervical spinal nerves and as trophic changes if the disease becomes chronic. For example, in recent disease of the upper part of the lung the stimuli result in almost constant contraction of the accessory muscles. At first the muscles may sometimes appear enlarged; at other times they present increased prominence due to shortening through contraction. On palpation these muscles feel hard and rigid. However, provided that the stimulation in the lung continues, in due time atrophy occurs in the muscles.

Apparently the signs you have observed are the result of direct stimulation of the sensory nerves of the muscle, which reflexly causes contraction of the part of the muscle involved so as to deviate the nuchal septum to that side and in a similar manner results in reflex changes of the superficial tissues.

VITAMIN E

To the Editor:—Is vitamin E in 100 mg. doses four times a day of value in the treatment of coronary disease?

M.D., Kansas.

ANSWER.—Two years ago vitamin E was recommended by two Canadian physicians as useful in the treatment of heart disease from various causes, including rheumatic, coronary and hypertensive, as well as of congestive heart failure. Since then there has been no carefully controlled clinical series reported, although various clinics have tried this material. Consensus was well expressed at a panel discussion on cardiac therapy at the meeting of the American Medical Association in Atlantic City, N. J., in June 1947, as follows: "Vitamin E is of no value in coronary heart disease, hypertension or rheumatic heart disease. The original claim that it is of benefit can be attributed to ceremonial therapy."

SYRUP OF IPECAC

To the Editor:—Please discuss use of syrup of ipecac in paroxysmal auricular tachycardia. What is the dosage? How quickly does it work and how long does the effect last?

M.D., New York.

ANSWER.—Syrup of ipecac should be reserved for obstinate and severe cases of paroxysmal auricular tachycardia, preferably proved by electrocardiogram as the ipecac produces such disagreeable symptoms. Vomiting is induced as the result of a vagal effect, which is the mechanism responsible for the control of the paroxysms. Dosage of 7.5 to 15 cc. (2 to 4 drachms) is most effective. The effect starts fifteen to thirty minutes after administration and lasts for about half an hour.

DERMATITIS OF EXTERNAL AUDITORY CANAL

To the Editor:—About five years ago the wax in my ears became more abundant and inspissated, resulting in frequent occlusion of the external auditory canal. Two years later itching in the outer end of the canal began, and occasionally acute exacerbations occurred with cellulitis and enlargement of lymph nodes. Eighteen months ago after swimming in a pool at a New York hotel an infection from Aspergillus occurred. This was apparently relieved by the application of "cresatin." Itching and cellulitis was believed to be due to seborrheic dermatitis, as I have pronounced infection of the scalp. Apparently Aspergillus infection did not recur. Recently another fungous infection occluded both ears completely in a matter of two or three days (swimming again!). "Cresatin" was again successfully used. If the cellulitis of the external auditory canals is untreated it recurs frequently and during attacks there drains from the canals serum which sometimes has the odor of unwashed feet. "Monarden" (a salicylic acid, benzoic acid chloromercuri carvacrol preparation, Smith-Dorsey), "pragmatar" (a modified coal tar preparation, with sulfur and salicylic acid, Smith, Kline and French) and other preparations have been used to keep the dermatitis and cellulitis in abeyance. Recently a fungicide containing, among other things, salicylic acid and iodine in an oil base has been used on the advice of a dermatologist. Now he wants to use roentgen radiation and states that my trouble is probably caused by a fungus. Some dermatologists are opposed to the use of roentgen therapy for dermatitis. What should I do? So far nothing seems to have been curative. Are cultures and smears for fungi accurate (when negative) for ruling out a diagnosis?

M.D., California.

ANSWER.—Before any treatment is instituted, the cause of the condition should be ascertained. Repeated cultures and subcultures on Sabouraud's medium may establish a fungous origin. Monilia are often the cause of dermatitis in the external auditory canal. If fungi are found to be the cause, then fungicides are indicated. Some of the newer ones are "salinidol" (contains salicylanilide 5 per cent and "carbowax" 95 per cent: Doak Co., Inc.), "salicylanilide phemerol cream" (Parke, Davis & Company), "desenex" (zincundecate, Wallace & Tiernan Products, Inc.) and "decupryl" (a preparation of undecylenic acid and copper undecylenate, Crookes Laboratories).

If fungus cannot be discovered, then an otologist should examine the canal and tympanum for chronic granulations. If found, these should be appropriately treated. If neither fungi nor chronic granulations are the cause of the condition, then the treatment should be for chronic eczema, such as has already been used to control the attacks. Recurrences may be prevented by refraining from scratching or touching the ears and by treating seborrhea capitis, if present. Roentgen therapy in filtered fractional doses given by a skilled dermatologist may be of value.

BODY ODOR

To the Editor:—An unmarried woman aged 24, complains of a "coal gas" odor about her which she maintains is most persistent while she is engaged in her employment as a bank teller. I find nothing relative to this condition, and she is now under my care for acne. I am trying to rule out any organic basis for her complaints. I have not detected this odor about her, but she states that her co-workers have complained to her and she is afraid of losing her job. All examinations, including an ear, nose and throat examination by a specialist, are negative. She states that this condition has persisted for the last five years.

M.D., Illinois.

ANSWER.—Could it be that a sulfur preparation which this woman is using for her acne is responsible for the odor? If not, one must consider those conditions which are usually credited with causing body odor such as: gas escaping from the bowel without the knowledge of the person; decomposition of sweat, sebum or urine on the skin or clothing; body discharge, as from the ears or vagina, or hyperhidrosis. It is said that certain foods can produce odors, particularly spices like garlic. Nervous influences, especially in hysterical persons, are said to emanate body odors. Occasionally an odor is transferred to the clothing from that of another member of the family whose clothing has been permeated by an odor from material used in an occupation. Finally, in some persons the odor is entirely in the imagination—an obsession or phobia much like acarophobia.

COMMON BEHAVIOR DISTURBANCES IN THE FIRST TWO YEARS OF LIFE

BENJAMIN SPOCK, M.D.
Rochester, Minn.

Read Before the Section on Nervous and Mental Diseases at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947

From the Department of Neurology and Psychiatry, the Mayo Clinic, and the Rochester Child Health Project

Significant behavior disturbances in babies are relatively infrequent during the first year of life as compared with the second, mainly because there are relatively few occasions for conflict between mother and infant. On the other hand, anxiety and weeping spells are common in the mother at the start. In our civilization, she may take her first baby home without any previous experience to accustom and reassure her. Prenatal classes are of some value but do not take the place of that everyday familiarity with the live baby which is the lot of young women in cultures more primitive and communal than ours.

A number of pediatricians, psychiatrists and obstetricians have recently become interested in the possibility of making the lying-in period more natural and reassuring. They have felt that the usual practice of relegating babies to a nursery, from which they are brought to their mothers only at intervals, and the tendency to let breast feeding go by default have inadvertently given the inexperienced mother the initial impression that she is of little importance to her baby and that its care can be entrusted only to medical experts. The so-called "rooming-in" arrangement is being experimented with in Detroit and elsewhere. The baby's crib remains in the mother's room, so that she can become familiar with his noises, moods, movements and appetite, and so that she can feed him on the breast when he is hungry, rather than according to the clock. Preliminary reports suggest that the effect is good, not only on mothers and babies but also on fathers. In conventional obstetric arrangements, the father is apt to feel like a rank outsider, a germ carrier from whom the baby must be shielded. In the "rooming-in" arrangement, he, and he alone, is allowed to visit, which allows him to think of himself as an acceptable member of the family at this formative stage of his development.

There has been a growing tendency in the last few years to discard the rigidity of feeding schedules, which in the past has probably done harm in encouraging mothers to become tense and arbitrary. A number of pediatricians are now recommending that the baby be fed when he seems hungry, irrespective of the hour. Although the method has a solemn name, "the self-demand schedule," and sounds newfangled, it is obviously nature's own, which was used by the entire human race until the turn of the century. A better term might be "self-regulated schedule." Surprisingly, or perhaps not so surprisingly, most babies are found to work themselves onto a fairly regular schedule in a short time. "Rooming in" and "self regulation" appear to be of real value in maintaining the mother's self confidence and giving her a relaxed attitude toward her child.

Feeding problems are the commonest ones during the first year in our culture. A few are started in the first weeks of life if the formula prescribed proves too large and if the nurse or mother has been encouraged to be arbitrary. The baby who, every time he falls asleep satisfied, gets the soles of his feet snapped and the nipple stirred vigorously in his mouth begins to lose his enthusiasm for food and to become balky and irritable. If the resistance to feeding becomes well established, it may last for years and have a harrowing effect on the personalities of child and mother.

A commoner time for feeding rebellion is when solid foods are first introduced. A majority of infants, despite their eagerness for calories, are initially doubtful about the first solid food. The taste, the spoon, the consistency, the method of swallowing are all new. Most of these skeptics decide after a few days that the substance is at least nutritious, and they gradually develop more enthusiasm. An appreciable minority, however, become increasingly intolerant as the days go by. If the struggle is kept up, the mother may report, at the end of ten days, that the baby is beginning to refuse his beloved bottle too. This spreading of the battle is a common phenomenon in children's disorders.

Attempts at forced weaning for which the baby is not ready often cause bad feeling. Psychiatrists have emphasized the danger of too early weaning, especially from the breast. But the exact pathogenesis of a weaning disturbance, as seen by the pediatrician, is not a simple matter of earliness or of deprivation of the breast. In the first place, a majority of young infants who are nursing at both breast and bottle show their ignorance of what is theoretically best for them by preferring the bottle. On the other hand, the baby who has been entirely breast fed for the first three or four months of his life is likely, if the breast supply is plentiful, to object violently to letting a rubber nipple pass his lips, and may prefer to starve for several days.

Some bottle-fed babies show a readiness for gradual weaning to the cup in the period between 8 and 12 months of age. They become less eager for the bottle, stop to play with the nipple and take milk readily from the cup. On the other hand, an appreciable number, even though they have taken willingly a little milk from the cup from as far back as 5 months of age, will, as they get to be about 9 months old, bat the cup away suspiciously or, pretending they have forgotten what to do, let all the milk run down the sides of the chin. It would seem as though a shrewdness coming on at this stage of development makes them suspect and fear that the bottle is about to be taken away. These are the babies who are generally devoted to the bottle, eyeing it during the solid part of their meal, stroking it and murmuring to it as they drink the contents to the last drop. Forced deprivation of the bottle at such a phase is likely to produce prolonged refusal to take any milk from the cup, unhappy behavior for a number of days and sometimes a complete hunger strike until the frightened mother gives in.

Breast-fed babies, on the other hand, rarely balk at weaning from breast to cup in the last quarter of the first year. In fact, they tend to wean themselves, nursing for shorter periods and gladly taking increasing amounts from the cup. There appear to be at least two reasons why they are more willing to be weaned than are bottle-fed babies of this age. Breast and cup are less similar than bottle and cup. It is the shift to something similar that an opinionated baby resists in weaning. Another factor is the 9 month old baby's desire to be independent during meals. He is now likely to want to sit up for his spoon feeding and, if he is bottle fed, to take the bottle away from his mother's hands and to drink the whole contents while sitting bolt upright. In other words, the breast-fed baby may prefer to wean himself not so much because suckling has lost its charm, but because he has advanced to the stage where he is impatient in the dependent, cuddled position.

The second year brings pronounced changes in an infant's personality and behavior and calls on the mother for entirely new resourcefulness and adaptability. She has become accustomed during the first year to his automatic cooperation. If she offered a teaspoon of spinach, he opened his mouth as eagerly as for applesauce. Even though he liked it less, he was too hungry to quibble. If it was convenient for her to have him in the playpen, she could put him there, toss him a couple of familiar toys and know that he would play happily. But at about a year he acquires independent locomotion and, with it, a charge of energy that keeps him going all day. He explores constantly, shakes table legs, pulls lamp cords, removes every book from the bookcase and climbs on anything he can reach. His ego is taking definite shape. He senses he is a separate person, entitled to wishes and a will of his own. He early learns to say "No" and uses it on all occasions, even in response to suggestions that appeal to him. He has learned no respect for authority and, when told "No, no" from across the room, is more likely to persist than desist. It seems as though he has a compulsive need to exercise his will power for its own sake.

As he becomes more insistent on his independence from his mother, he simultaneously becomes aware of his dependence. He may cry each time she leaves him alone. If he is allowed freedom to explore in the house, he scrambles back to her at regular intervals for reassurance. In the doctor's office he, who at 11 months was quite unconcerned about examination, now leaps to his feet and, yelling, tries to climb off the table into his mother's arms. He is now likely to be frightened by noisy, moving objects, like vacuum cleaners. Undoubtedly, it is part of his total pattern of emotional development that when he has the ability and the desire to explore away from his mother he also has the instinct to hurry back to her noisily when he meets something strange and potentially dangerous.

A majority of babies at about the age of 1 year show the same exaggerated arbitrariness in appetite that they show in other matters. Probably, the smaller rate of gain in weight and the discomfort of molar teething play a part in the sudden decreases in appetite that occur. But, over and above these, he shows an irritating choosiness. He refuses to touch the vegetable which yesterday was his favorite. He may turn against all his vegetables for weeks, and even months, at a time, or against cereal and his milk. The conscientious mother, sure of the importance of the balanced diet, is tempted to become bossy and insistent. The child's temporary dislikes of certain foods are turned into permanent hates, which often last for years. Certainly, more feeding problems begin during the second year than during any other period. The irritation of the frustrated mother and the balkiness of the child easily spread into other aspects of their relationship.

Psychiatrists, from data gained from older children and adults, have stressed the danger to the child's emotional development of too early and too rigorous toilet training. Pediatric observation would indicate that the earliness at which training efforts are begun is much less important than the reaction of the child and the attitude of the mother during the precarious second year. He is generally opinionated and touchy. He becomes increasingly aware of his bowel function and takes a possessive and proprietary attitude toward it. As he slips off the seat, he turns to admire his movement, sniffs it appreciatively and asks his mother to enjoy it too. If her attitude is overdemanding and intolerant, it is easy to see why she rubs him the wrong way. Actually, few revolts occur in the babies whose movements are naturally regular. They have their movements on the seat right after breakfast, before they have a chance to become impatient. It is the child who is naturally irregular whose mother is tempted to put him on too often and to insist that he stay on too long. The babies who are most prone of all to develop resistance are those who have experienced painfully hard movements. In fact, one painful movement may be enough to create a dread of the toilet that lasts six or eight months. Whatever the cause of the initial resistance, the mother's insistence increases the child's obstinacy, anxiety and guiltiness. When he eventually decides to give in and perform in the right place, he may show anxiety about other forms of dirtiness, too. Suppositories and enemas used after a training struggle has begun are resisted with rage and terror and hasten the character distortion.

This vital phase of ego formation is difficult for parents. They are not prepared by experience or teaching for the drastic changes. Arbitrary doctrines about diet and toilet training invite them into trouble. Small houses and apartments provide too few cubic feet per ego and too few harmless outlets for the expanding personality of the 1 year old child. The small number of children per family encourages parental overconcern. There tend to be too many prohibitions, too many demands and too many clashes. The child's outgoingness is blocked; his progress toward independence is impeded, and his awareness of self is intensified beyond what is ideal.

In the olden days, parents with poor qualities of leadership probably relied most on slaps. But the modern teaching that physical punishment is shameful has deflected them into forms of control such as chronic scolding, prolonged moral disapproval, warnings of the dangerous consequences of misbehavior, even excessive reasoning and overexplanation, which I believe bring about worse distortion of the malleable personality. These influences are manifested by the age of 2 years in tense, anxious, dependent, self-centered children and lay the groundwork for the formation of specific neuroses and character disorders.

Although the pediatrician cannot hope to change the mother's basic nature, I believe that he can give her prophylactic advice that minimizes the clashes. He should explain at the start that the baby will be a better judge than mother or pediatrician of how much he needs at each feeding, warn the mother when starting solids to give the child time to get used to them and advise against weaning until the child shows readiness, even though it is not until the middle of the second year. He can explain, before the child reaches the age of 1 year, that appetite is likely to change and that satisfactory substitutes which the child likes can be found. More pediatricians today are advising mothers to omit all toilet training efforts until toward the end of the second year, when the baby's awareness of bowel function and intense desire to imitate may induce him to think up the idea of going to the toilet himself. At least the mother should be warned against beginning her training efforts until she can exactly predict the timing of the movement, either because of the baby's regularity or because he begins to make some sign of readiness. It is possible to help the parent who is unimaginative or insecure to avoid some of the disciplinary clashes by describing how the house must be arranged so that most breakable objects are removed from reach, and enough harmless ones, like pots and pans and magazines, are left near the floor. Then the house-bound child has enough to occupy him without too many prohibitions. When inhibition is started, the main recourse of the parent should be a brisk, friendly removal of the child from the dangerous or breakable object and distraction to something else. Mothers also need to be urged to take small children outdoors often, to let them out of their carriages in places where they can safely be given some freedom and where they can become accustomed to other children.

We need also experimentation with some sort of guidance nursery or guidance playground where 1 and 2 year old children, too young to be left at nursery schools, could come to play.

ABSTRACT OF DISCUSSION

Dr. Karl M. Bowman, San Francisco: This is an ideal paper for every doctor and every parent to read. It shows that material can be presented in simple language and yet be of the highest scientific value; that is something which members of the medical profession, particularly psychiatrists, have not sufficiently learned. It illustrates that a great deal of fine research work can be done when working at a clinical level. Those of us in psychiatry would agree to practically all the things advocated here. This study represents the cooperative type of research in various fields of medicine, and the integration of psychiatry with pediatrics, which many psychiatrists have felt would be valuable for pediatrics and for psychiatry. Pediatrics has suffered from the laying down of rules about feeding, toilet training and the like; if the child did not conform, the fault was his, just as it is in certain types of psychotherapy. At one time, it was the patient's fault if he could not conform to the orthodox psychoanalysis, whereas now, in the recent book by Alexander and French, it is suggested that the treatment should fit the individuality of the patient, unless one is to force a specified type of treatment on the patient. I am particularly in favor of the idea of giving the poor father a little more ego help in this situation, for the common attitude in the hospital is that perhaps the father has had some responsibility for the child but that from now on he is less than nothing. There are two questions that I should like to raise. The first concerns this concept that the child resists being shifted from one thing to another which is similar but accepts more readily something dissimilar. Does Dr. Spock feel that this is a universal rule which would apply to all types of childhood training? If so, it is certainly very important. The statement about scolding and its pernicious effect I endorse heartily, and I should agree both with the chairman and with the author that one can be, incidentally, more brutal to a child with certain types of scolding and tongue lashing than with an ordinary spanking or slapping, and do the child's personality infinitely more harm.

Dr. Frederick H. Allen, Philadelphia: I shall confine my comments to two points brought out in this paper. The first emphasis that Dr. Spock places on the plan of bringing the infant into a more intimate relation with the mother from birth, I think, represents an important departure in this bacteriologic age, in which we have stressed a 100 per cent culture-pure atmospere for a child and some of the important emotional needs of the child and the parent have been neglected. Here, it has been recognized that the infant is a part of the family unit from the very moment of his birth. Here, he emerges as a person, an emergence that can never take place in isolation. His needs from the first moment of living bring him into relation with those who have to satisfy those needs. He gets his first experience in living not in the isolation of the nursery, but in the more intimate connection with the mother, who, at the same time, is getting her first experience with this particular child in fulfilling the important role of being a mother. This procedure recognizes that the mother is really the important person to take charge of the child from the very beginning. The second point is the emphasis that Dr. Spock places on the emergence of the negative in the child toward the end of the first year, and in a somewhat exaggerated way in the second year. Such behavior is the evidence of the emergence of a separate person, who is experiencing the first sense of his power. He exercises it in the very ways that Dr. Spock has so clearly stated. The sensitive understanding of this negative behavior, and the realization of its importance, reflected in the way it is handled, can determine the difference between a child who has a healthy way of asserting himself and one who has to continue and develop unhealthy patterns of saying no. This behavior presents a difficult dilemma for a parent, who must put limits and direction into the life of the child while allowing him some freedom to feel negative. The autocratic parent may try to wipe out this apparent rebellion, and the indulgent or timid parent may fail to provide the support a child needs as he is discovering what he can or cannot do. Both extremes represent a failure to understand the importance of the negative in a child's behavior. It is important that Dr. Spock brought out the relation between dependence and independence and to emphasize that independence really grows out of dependence; dependence is not a phase to rush a child over quickly in the urge to shove him into independent living. The healthy aspect of independence means just what the word itself signifies; independence is always in relation to dependence.

Dr. Benjamin M. Spock, Rochester, Minn.: I am glad that Dr. Bowman caught me in that generalization about babies always resisting more strongly the shift to something similar than to something different. I meant it only in regard to weaning behavior. The bottle-fed baby who refuses milk from a cup will often take it from a spoon. The baby who refuses milk from his regular white cup may take it if it is put into a red cup or if it is changed from warm to ice cold.

LEPTOSPIRAL INFECTIONS

A Survey

JOSEPH G. MOLNER, M.D., M.P.H.
KARL F. MEYER, M.D., Ph.D.
and
HERBERT A. RASKIN, M.S.P.H.
Detroit

From the literature on leptospiral infections in the United States, Weil's disease (spirochetal jaundice) and canicola fever,[1] it would appear that these diseases have been recognized as a problem in preventive as well as curative medicine, as prophesied editorially in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION ten years ago.[2] The research devoted to this subject since Weil made his clinical observations in 1886 [3] has resulted in much valuable information. The spirochete Leptospira icterohaemorrhagiae was established as the causative organism of Weil's disease in 1915.[4] Laboratory methods for its diagnosis were introduced in 1922.[5] The clinical manifestations, pathology, animal reservoirs, epidemiology and geographic distribution have been extensively discussed in the literature.[6] A comparable, but less complete, elaboration of detail is also available for canicola fever.[7]

Despite this wealth of data, however, leptospiral infections still challenge the public health officer, the clinician, the bacteriologist, the laboratorian, the veterinarian—in fact, the entire field of medical science. It is the purpose of this survey to evaluate the all-important role of these infections among the acute febrile diseases and to indicate what steps need be taken to meet this problem.

Although leptospiral infections have been reported from practically every country in the world,[7a] the number of cases in the United States appears to be disproportionately low, especially when compared with the incidence in Continental Europe and Great Britain. In the Netherlands, for example, the diagnosis was established in 808 cases between 1929 and 1937.[7a] In France, 263 proved cases were found in the interval from 1924 to 1932, and there were at least 248 cases in Great Britain between 1924 and 1938.[8] In contrast, examination of the medical literature of the United States revealed only 228 cases reported in this country.[9] Since Ashe and associates [10] have shown that North Americans possess no particular immunity to these infections, and since, as will be shown, there is no evidence of less exposure to leptospiras in the United States, such a discrepancy would seem to be due to failure to recognize or to report cases.

The reason for this failure is twofold. First, the clinical manifestations of these conditions are not well enough known to be considered in the differential diagnosis of acute febrile diseases. Second, and perhaps of greater importance, is the fact that the diagnosis is almost entirely dependent on laboratory findings, and there are few laboratories in the United States adequately equipped to do leptospiral agglutination tests. As a matter of fact, the recent work of Ward and Turner,[11] in Baltimore, and of Tiffany and Martorana,[12] in New York, supports the contention of most authors that leptospiral infections are not difficult to detect if one looks for them. The findings in the Detroit survey, as will be discussed, further support these observations.

It is most likely that only the striking, easily recognized severe forms, with their characteristic jaundice, hemorrhage and renal disorders, have been diagnosed and reported. It is known that mild forms also occur which undoubtedly far outnumber the severe ones. Therefore, since only about one-half the patients with these infections have jaundice, as originally predicated by Weil himself and emphasized by subsequent authors, it is readily understandable that unless physicians are aware of the diseases many cases will pass unrecognized. It is interesting to note that despite the availability of specific laboratory service in the Detroit area, in all 78 cases the diagnosis was made either in the second stage of the disease [13] by agglutination tests or at autopsy.

If earlier diagnosis and more frequent recognition of leptospiral infections are to be accomplished, the icteric and hemorrhagic features must yield to the epidemiologically more important first stage, characterized by sudden onset, severe myalgia, especially in the calves, fever, chills and conjunctival injection. Polymorphonuclear leukocytosis is almost constantly present. Confirmation of diagnosis by laboratory procedures may include blood culture, animal inoculation and serum agglutination tests. The last is considered to be the most dependable means available.

Before discussing the series of 78 cases in the Detroit area, certain characteristics of leptospiral infections reported in the United States may be noted. The first case of leptospirosis in the United States was reported by Stimson in 1905.[14] He observed an organism, which he called "Spirocheta interrogans," in the tissues of a patient who died during an outbreak of yellow fever. Although Stimson failed to recognize the organism, Sellards [15] in 1940 identified it as Lept. icterohaemorrhagiae. Wadsworth and associates [5] in 1922 reported a case of Weil's disease occurring in one of his laboratory assistants, and since that time 228 cases of leptospiral infections have been reported in the medical literature of the United States—222 of Weil's disease and 6 of canicola fever. Tables 1, 2 and 3 present a summary of these cases by geographic location and date of onset.

---

[1] Other leptospiral organisms of pathogenic importance to man have never been reported in the United States, viz., Leptospira grippotyphosa, Leptospira hebdomidis and Leptospira autumnalis.

[9] Leptospiral infections are not generally viewed by members of the medical profession as "reportable" diseases, even though so designated by law in many states. Thus, data are not available in official compilations of vital statistics. The effect of reporting on "incidence" is illustrated by the experience in the Netherlands.[7a] Whereas in the three year period immediately preceding compulsory notification of these diseases there were reported 69 cases, such reports reached the total of 481 in the following three years.

[15] Sellards, A.: Tr. Roy. Soc. Trop. Med. & Hyg. **33:** 545, 1940.

A review of these tables reveals many interesting facts. It is apparent that the period from 1935 to 1941 represents one of increased case finding, reflecting a general interest in these infections at that time, both in this country and abroad.[16] Cases have been reported from twenty-three states and the District of Columbia, but over 70 per cent of the cases occurred in only nine states. The seasonal distribution of these cases (table 3) compares favorably with reports from other countries, 60.6 per cent occurring in the four month period between June and September. Of the 228 reported cases, in only 178 was the end result of the illness discussed. In this series the fatality rate was 24.7 per cent.

TABLE 3.—*Cases of Leptospiral Infections Reported in the Literature of the United States According to Month of Onset**

	No. of Cases		No. of Cases
January	6	July	17
February	7	August	21
March	5	September	21
April	2	October	8
May	7	November	9
June	15	December	6

* A total of 127 cases in which month of onset was procured.

Although the 78 cases of leptospiral infection in the Detroit area[17] represent over one-fourth the total number of cases reported in the United States, this need not imply an increased incidence in this area. It is probably indicative of a high degree of interest motivated by the availability of complete, adequate and specific laboratory facilities in Detroit.[18] Thus, the diagnosis was established in many clinically and epidemiologically suspected cases which undoubtedly would otherwise have been missed.

Despite the apparent awareness of these diseases and the immediate availability of laboratory aid, jaundice developed in all 78 cases. As a matter of fact, it has been repeatedly stated that jaundice was the lead that brought these diseases to differential diagnosis and the accessibility of laboratory agglutination tests, dark field examination, cultures and animal inoculation established the diagnosis. In view of the opinion previously stated that in only about one-half the cases of these infections is jaundice present as a clinical entity, it is obvious that even the relatively large incidence reported from this area is still a significant understatement of the facts.

It should be noted (table 4) that this series of 78 cases includes only proved cases of leptospirosis, verified by an agglutination titer of diagnostic significance (1:300 +) or by autopsy. Many cases in which the diagnosis was based on clinical observation without laboratory confirmation are not included. Thus, it may be assumed that had laboratory examination been made in these instances the number of cases reported would have been appreciably increased.

EPIDEMIOLOGY

Age and Sex Incidence.—Because of an occupational predisposition, these infections would seem to be most

---

[16] It was usual to find that the first case reported in a given area was followed by publication of additional cases.

[17] Of the cases reported in the Detroit area, 13 have been previously published. Molner and Kasper,[20a] Molner and Meyer,[23c] Martmer.[20b] Clapper, M., and Myers, G. B., Clinical Manifestations of Weil's Disease with Particular Reference to Meningitis, Arch. Int. Med. 72:18 (July) 1943. Gordon, W. H., and Feldman, N.: M. Rec. 51:209, 1940.

[18] The Detroit Department of Health has had such facilities available since 1937 in its own laboratory and in cooperation with the National Institute of Health, Washington, D. C., and the George William Hooper Foundation, University of California.

TABLE 4.—*Cases of Leptospiral Infections in the Detroit Area*

Case No.	Sex	Age	Onset of Illness	Outcome of Illness	Agglutination Reaction: Lept. Icterohaemorrhagiae	Agglutination Reaction: Lept. Canicola	Exposure to Leptospiras
1	M	46	July 1937	Recovery	1:30,000	—	Poultry worker
2	M	16	June 1938	Recovery	1:3,000	1:300	Caddy; waded in Rouge river; pet dog had positive agglutination reaction to Lept. icterohaemorrhagiae (1:100,000)
3	M	34	November 1938	Fatal	1:10,000	—	Poultry worker
4	M	17	August 1938	Recovery	1:30,000	—	Moved wet lumber contaminated with rat urine; waded in Clinton river
5	M	38	October 1938	Recovery	1:10,000	—	Dug cesspool in trailer camp, wading in Fox creek, a sewer outlet
6	M	3	January 1938	Fatal	1:30,000	—	Pet dog ill with Weil's disease; neighborhood rats positive agglutination reaction to Lept. icterohaemorrhagiae
7	F	14	March 1938	Recovery	1:20,000	—	Unknown
8	M	32	February 1938	Recovery	1:30,000	—	Poultry worker
9	M	29	November 1939	Recovery	1:30,000	1:100	Poultry worker
10	M	46	September 1939	Fatal	1:30,000	—	Poultry worker
11	M	27	June 1939	Fatal	1:30,000	—	Poultry worker
12	M	49	November 1939	Fatal	1:300	—	Set and handled traps in rat-infested beer garden
13	M	55	December 1940	Recovery	1:100,000	1:100	Poultry worker; home also infested
14	M	21	January 1940	Recovery	1:30,000	1:10,000	Poultry worker
15	M	50	October 1940	Fatal	1:1,000	1:300	*Plumber; frequent basement jobs; also trapped rats at home*
16	M	47	June 1940	Recovery	1:30,000	—	Trapped rats at home; heavy infestation of food, etc.
17	M	41	May 1941	Recovery	1:30,000	1:300	Home infestation; rat bite 6 wk. previously
18	M	46	January 1941	Recovery	1:10,000	1:300	Poultry worker
19	M	64	February 1941	Fatal	1:30,000	—	Unknown
20	M	39	November 1941	Recovery	1:100,000	1:1,000	Washed automobiles in rat-infested garage
21	M	37	November 1941	Recovery	1:100,000	1:100	Junk collector; killed rats in alley; constant contact
22	M	51	June 1941	Recovery	1:1,000	1:30	.partment; resides in "flophouse"
23	M	52	November 1941	Recovery	1:100,000	1:1,000	*rats also found in bedroom*
24	M	39	August 1941	Recovery	1:100,000	1:100	n rat-infested garage; home infested: in food, etc.
25	M	57	August 1941	Recovery	1:10,000	1:300	Fish market worker; sets and cleans traps
26	M	7	July 1941	Recovery	1:100,000	1:100	Swimming in Rouge river
27	M	33	December 1941	Recovery	1:100,000	1:1,000	Worked in rat-infested packing room in bottling works
28	M	40	December 1941	Recovery	1:100,000	1:1,000	Poultry worker
29	M	38	May 1941	Recovery	1:800	1:200	Poultry worker; pet dog killed rats, ill
30	M	47	June 1942	Fatal	1:30,000	—	Ground wire man, frequently worked in alleys
31	M	46	January 1942	Fatal	1:30,000	1:30	Alley picker; *storeroom infested with rats*
32	M	50	December 1942	Fatal	1:30,000	—	Resided in "flophouse"
33	M	38	September 1942	Recovery	1:30,000	—	Poultry worker
34	M	33	August 1942	Recovery	1:30,000	1:100	Fish market worker
35	M	31	September 1942	Fatal	1:30,000	—	Poultry worker
36	M	18	May 1942	Recovery	1:30,000	1:100	*Frequently played in alley*
37	M	46	August 1942	Recovery	1:30,000	1:10,000	Porter in rat-infested beer garden
38	M	28	July 1942	Recovery	1:100,000	1:2,000	Alley picker; resided in "flophouse"
39	M	51	March 1942	Recovery	1:30,000	1:3,000	Poultry worker
40	M	39	August 1942	Recovery	1:30,000	1:100	Fish market worker
41	M	23	March 1942	Recovery	1:30,000	—	Home and neighborhood infested with rats
42	M	30	October 1942	Fatal	—	1:10,000	Dog kennel in yard; numerous rats
43	M	39	October 1942	Fatal	1:300	1:100	Unknown
44	M	44	October 1943	Recovery	1:30,000	—	Poultry worker
45	F	35	March 1943	Recovery	1:1,000	—	Neighborhood and home infested
46	M	45	August 1943	Fatal	1:1,000	1:10	Unknown
47	M	49	January 1943	Fatal	1:30,000	—	Pet dog positive agglutination reaction to Lept. icterohaemorrhagiae
48	M	28	July 1943	Fatal	1:3,000	1:30	Neighborhood and home infested
49	M	26	August 1943	Fatal	1:10,000	—	Unknown
50	M	9	November 1943	Recovery	1:30,000	—	Neighborhood and home infested; scratched by sick cat
51	M	55	July 1943	Fatal	Autopsy	..	*Factory tunnel protection, job site and home infested;* three cats ill; pet dog killed rats
52	M	31	August 1944	Fatal	Autopsy	..	Resided in "flophouse"
53	M	57	September 1944	Recovery	1:30,000	1:30	Launderer in slaughterhouse; dirty clothes left overnight
54	M	59	July 1944	*Fatal*	*1:1,000*	1:30	*Plumber; frequent jobs in basements*
55	M	54	March 1944	Fatal	1:30,000	—	Resided in old rat-infested barn in **city** food prepared here
56	M	41	August 1944	Fatal	1:1,000	—	Home infested; "scratched while in bed"
57	M	47	October 1944	Recovery	1:30,000	1:300	Junk dealer; alley collection
58	M	46	May 1944	Fatal	Autopsy	..	Cook in rat-infested building
59	M	37	November 1944	Fatal	1:30,000	—	Dog ill from rat bite
60	M	39	September 1944	Recovery	1:30,000	1:1,000	Tanner; dead rats found in vats
61	M	18	November 1944	Recovery	1:30,000	—	Cleaning drugstore basement; porter
62	F	26	September 1944	*Fatal*	1:300	1:30	Home infestation
63	M	50	May 1944	Fatal	1:300	—	Unknown
64	F	49	October 1944	Fatal	1:10,000	1:30,000	Poultry worker
65	M	40	June 1944	Fatal	Autopsy	..	Unknown
66	M	44	March 1944	Fatal	Autopsy	..	Home and job site at foundry infested
67	M	34	November 1945	Recovery	—	1:1,000	Cement finisher, basement work; home infested
68	M	43	October 1945	Recovery	1:1,000	1:1,000	Poultry worker
69	F	29	September 1945	Recovery	1:300	1:10,000	Dishwasher
70	M	54	March 1945	Fatal	1:10,000	—	Contractor, building basements, sidewalks, etc.
71	M	56	August 1945	Recovery	1:3,000	1:1,000	Poultry worker
72	M	43	March 1945	Recovery	1:3,000	1:30,000	Slaughterhouse worker
73	M	41	February 1945	Fatal	1:800	1:1,000	*Pet dog ill 2 wk. prior to patient's onset*
74	M	21	September 1945	Recovery	1:1,000	1:10,000	Slaughterhouse worker
75	M	53	January 1946	Recovery	1:10,000	—	Plumber, frequent jobs in basements
76	M	49	January 1946	Recovery	1:10,000	1:300	Walked in rat-infested alley in bare feet
77	M	45	October 1946	Recovery	1:1,000	—	Fish cleaner and peddler
78	M	24	April 1946	Recovery	1:1,000	—	Slaughterhouse worker

prevalent among men; and, indeed, such was the case in this series (table 5). Among the 78 cases reported, 73 of the patients were male (93.4 per cent) and only 5 female. The age distribution of these cases provides further evidence of an occupational relationship. It may be noted that 89.7 per cent of the cases occurred in the employable age groups over 20 years of age. A similar age-sex distribution was found to exist among the reported cases in the United States.

TABLE 5.—*Cases of Leptospiral Infections in the Detroit Area: Distribution by Age Groups*

Age Group	No. of Cases	Per Cent, Total
All ages	78*	100.0
Under 10	3	3.8
10 to 19	5	6.4
20 to 29	10	12.8
30 to 39	20	25.6
40 to 49	24	30.8
50 to 59	15	19.2
60 plus	1	1.3

* The series includes 5 female patients, aged 14, 26, 35, 59 and 49.

Seasonal Aspects.—Leptospiral infections generally show no definite seasonal variation, although many authors report a higher incidence between June and November, the largest number occurring in July, August and September. Such reports have usually been based on the work of Walch-Sorgdrager,[7a] of the Netherlands. In the United States, as previously indicated, cumulative reports show a larger proportion of cases in the months of June through September. However, in the Detroit series this was not so. Table 6 shows the appearance of sporadic cases throughout the year, except for an almost imperceptible increase during the period from August through November.

TABLE 6.—*Leptospiral Infections in the Detroit Area: Distribution by Month of Onset*

Month	No. of Cases	Per Cent, Total
Total	78	100.0
January	7	9.0
February	3	3.8
March	8	10.3
April	1	1.3
May	5	6.4
June	7	9.0
July	5	6.4
August	11	14.1
September	8	10.3
October	9	11.5
November	10	12.8
December	4	5.1

Fatality Rate.—As was previously stated, the fatality rate for cases reported in the United States literature is approximately 25 per cent, whereas among the 78 cases in the Detroit area there were 31 deaths, a rate of 39.7 per cent. Variations in virulence and susceptibility[19] may explain the difference between the two rates. However, it has been indicated that the Detroit series represents only severe forms of leptospiral infections, forming a group in which a high fatality rate would be expected.

All authors agree that most of the known infections with Lept. icterohaemorrhagiae come from direct contact with the excreta of rats; recent evidence indicates that dogs are susceptible to this infection from contact with rats and may act as an intermediary between the rat and man.[20] These animals carry the organisms the epithelium of the renal tubules and excrete them with the urine. Soil, food and water so contaminated can become potent sources of infection.

Rats from all parts of the world have been examined, and as high as 48 per cent of the rats examined have been found to be vectors of Lept. icterohaemorrhagiae.[21]

Lept. canicola produces a disorder in dogs that resembles human icteroid infections: and Schuffner,[24] In 1938, Meyer and associates[22] reported renal leptospiral infections in 16 per cent of rats from the Detroit area and a sample survey conducted by the Detroit Department of Health in 1939 showed that about 25 per cent of the rats in this area were carriers of the organism. Positive serum agglutination reactions in dogs have been reported from many areas of the United States, with rates as high as 38.1 per cent.[23] Walch-Sorgdrager[7a] and Meyer and associates[7b] were able to isolate Lept. canicola from persons with an infection resembling Weil's disease. Presumably, Lept. canicola is a canine infection transmissible to man through close contact with the dog.

Most cases of leptospiral infections reported from all over the world show a close association with rats, dogs or their infected excreta, usually in moist, damp or wet environments. In other cases the disease has been contracted while swimming or bathing or from accidental immersion in polluted bodies of water. Certain occupations show an increased degree of exposure to these organisms, and Stiles and associates[20c] discussed these diseases as a compensable occupational hazard. The cases reported from the Detroit area show the same epidemiologic features.

TABLE 7.—*Leptospiral Infections in the Detroit Area: Summary by Manner of Exposure to Leptospiras*

Occupational exposure	49
Poultry worker	18
Slaughterhouse worker	5
Alley worker *	5
Fish house worker	4
Porter	4
Plumber	3
Cement worker	2
Auto washer	2
Packing room	1
Factory tunnel protection	1
Tanner	1
Cook	1
Dishwasher	1
Foundry	1
Neighborhood and residence infestation	12
Accidental immersion in water	4
Pet dog	4
Accidental contact in alley	2
Unknown	7

* These include rag picker, alley picker, junk peddler and ground wireman.

Table 7 is a summary of the cases reported in this area grouped according to the manner of exposure to the leptospira, as determined by epidemiologic investigation of each case by the staff of the Detroit Department of Health. With the exception of the 7 cases of unknown exposure (table 4), in every instance there was found the characteristic contact with rats and/or dogs. The emphasis placed on occupational exposure is evident here in the fact that 49 persons (62.7 per cent) had been so exposed. Each of these patients gave a history of rat infestation of his job site. In addition, 9 persons also gave a history of rat infestation of their place of residence and residential neighborhood, thus presenting a dual possibility of exposure to the organism. The predominance of poultry workers among the first patients whose disease was diagnosed in this area led to an interesting experiment conducted by us in which leptospiras were discovered on the work tables of these establishments.[25]

In all the cases in which rat-infested homes were reported, contamination of food, presence of rats in bedrooms and bathrooms, handling of rat traps and carcasses and other sources of exposure were indicated (table 4). In 3 of the cases in which pet dogs were handled, the dogs showed positive agglutination reactions, while in a fourth the dog became ill after a rat bite. In the last case, rats trapped in the neighborhood gave positive agglutination reactions, and the organism was demonstrated in macerated specimens of the kidneys. Contact with pet dogs was also a possible source of exposure in 4 additional cases.

In the cases in which exposure apparently resulted from accidental immersion in polluted water, rats trapped in the immediate area were studied and leptospiras were demonstrated in each case. Of the 7 cases with unknown history, 6 were fatal, with death intervening before any epidemiologically valid history could be obtained. In the remaining case (7, table 4) no definite exposure to either rats or dogs was revealed.

Thus far, the epidemiologic factors of age, sex, seasonal variation and manner of exposure to leptospiras have been discussed. It has been indicated that, with only minor variations, the cases in the Detroit area were similar to those reported elsewhere in the United States and other parts of the world. But with further correlative analysis of the agglutination reactions and the manner of exposure to leptospiras (table 4), certain questions arise relative to the differential diagnosis of infections with Lept. icterohaemorrhagiae and Lept. canicola and the epidemiologic relationships of these organisms.

Clarification of the relationship of Lept. icterohaemorrhagiae and Lept. canicola has yet to be determined. Various conflicting factors must be reconciled. Some authors claim a strong cross agglutination factor between the two organisms,[7a,c] while others (Rosenbaum [7d]) consider that only a mild coreaction exists.[26] Further, the effects of various strains of the organisms, their antigenic qualities and the potential production of antibodies require further study. In addition, the time of withdrawal of serum during the course of illness also greatly complicates the differential diagnosis.

At first it was believed that Lept. canicola was merely a variant of Lept. icterohaemorrhagiae. Morphologically, even with the electron microscope,[27] the two organisms appear identical. At present, however, it is generally agreed that leptospirosis canicola represents a distinct disease in that it varies from typical Weil's disease immunologically, in mortality rate, in its virulence in test animals and in some clinical characteristics.[7a,d]

In 38 cases of the Detroit series, it is obvious that the infection is that of Lept. icterohaemorrhagiae Agglutination reactions for Lept. canicola in these cases were either negative or the titers extremely low (less than 1:30) [28] In 2 additional cases (42 and 67, table 4) the diagnosis was clearly one of leptospirosis canicola. In the 5 cases in which the diagnosis was made at autopsy, identification of the specific organism was, of course, impossible.

However, the exact differential diagnosis in the remaining 33 cases is not so clear. As indicated in table 4, the agglutination titers of the serums of these patients are of apparently diagnostic significance against strains of both Lept. icterohaemorrhagiae and Lept. canicola. Which of these cases represent infection predominantly with Lept. icterohaemorrhagiae or Lept. canicola, and which cases represent mixed or dual infections is difficult to say.

According to the work of Walch-Sorgdrager,[7a] confirmed by Meyer and associates, there are cases in which one serum reacts with another strain in a manner which is termed *para-specific (associated reaction)*, since it rests on the similarity of the two strains in respect to their antigenic structure. It has been shown that both rat and human strains of Lept. icterohaemorrhagiae give paraspecific reactions with Lept. canicola serum. At times, this reaction has been very strong, yielding a value up to one-third the specific titer. The titer generally served to distinguish between these paraspecific reactions and the main (specific) reaction. Identification of the organism was possible from the fact that the reaction reached the level of the full specific titer with one or more anti-leptospira-icterohaemorrhagiae serums, but did not with the anti-leptospira-canicola serum, and also from the fact that the paraspecific reaction was apt to be weaker when the test was repeated or when a serum produced with heated antigen was used. Except for this difference in titer, the main and the paraspecific reactions cannot be distinguished with certainty.

---

[25] In the poultry houses studied there was found a heavy rat infestation, due to general lack of good housekeeping, blood, water and offal not being completely removed. The work tables were washed with Ringer's solution early in the morning, after having been exposed, as was the usual practice, during the night. Inoculations were made in guinea pigs, resulting in jaundice and death, with the pathologic lesions of Weil's disease. *At a later date, after the normal day's labor had been completed,* one table top was washed with a dilute solution of hydrochloric acid. The following morning no leptospiras were demonstrable in sample washings. This seems to verify other experimental and epidemiologic observations that leptospiras do not remain viable in an acid medium.

[26] In certain of the agglutination reactions indicated in table 4, the titers could perhaps *be explained on a cross agglutination basis. But there* are others that show a very high dilution for Lept. icterohaemorrhagiae and a negative reaction for Lept. canicola. This merely complicates the picture a little more.

[27] Morton, H.: J. Bact. **45**: 143, 1943.

[28] Blood serums from the 78 cases underwent agglutination tests for both Lept. icterohaemorrhagiae and Lept. canicola. These tests were conducted in the laboratory of the Detroit Health Department; at the National Institute of Health, in Washington, D. C., or at the George William Hooper Foundation, at the University of California; in many instances a single serum was examined at all three laboratories. Unfortunately, the agglutination reaction for Lept. icterohaemorrhagiae in most instances does not represent the "end point" of the reaction but merely an arbitrary "stopping point." Thus, it is impossible to derive a true representation of the relationship of the immunologic characteristics of these organisms from these data.

It would, therefore, seem probable that in many of these 33 cases the infection was with Lept. icterohaemorrhagiae and that the agglutination reaction noted represented merely a paraspecific reaction with Lept. canicola. There is always a possibility that the paraspecific reactions are anamnestic, since Lept. canicola infections may be latent. Man is probably frequently exposed to, and even infected with, these organisms Repeated serologic tests in combination with absorption undoubtedly would have confirmed the etiologic agent in these infections. Unfortunately, records for repeated agglutinations in the Detroit series are not available.

Unless one of these presumptive explanations is admitted for all these cases, the epidemiologic characteristics of Lept. canicola infections must be subjected to reconsideration. Although Lept. icterohaemorrhagiae is known to infect many animals (dogs, field mice, cats, pigs, foxes, mongooses, poultry, bandicoots, horses and rats), Lept. canicola has never been shown to infect naturally any animal but the dog. Lept. canicola has never been demonstrated in the rat population.[29] Even experimental inoculation of rats by Walch-Sorgdrager showed that whereas the rat was nearly always a carrier of Lept. icterohaemorrhagiae, it did not become a carrier of Lept. canicola. The latter organism appeared in the kidney of this animal only transiently and was not excreted in the urine.

It is interesting to note that even though 35 patients showed positive agglutination reactions with Lept. canicola in dilutions of 1:100 or more, only 4 of these patients indicated possible exposure to leptospiras from dogs, the remainder indicating known exposure to rats exclusively. Although contrary to all existent laboratory evidence, the possibility of the rat acting as an agent in the transmission of Lept. canicola infection must not be disregarded.

SUMMARY AND CONCLUSIONS

A series of 228 cases of leptospiral infections reported in the United States literature is reviewed. In comparison with the incidence in Europe and Great Britain, this total seems disproportionately low. The discrepancy appears to indicate diagnostic failure, probably due to a lack of awareness by American physicians of the clinical, epidemiologic and laboratory aspects of these infections. Even though the 78 cases of the Detroit area, reviewed in this paper, represent the largest single series ever reported in the United States, and despite greater availability of specific laboratory facilities in this area, the factor of diagnostic failure still obtained.

The Detroit survey revealed a number of additional factors. The role of rats and dogs in the transmission of these diseases, previously observed and recorded, was confirmed and emphasized. However, certain other aspects of leptospiral infections were revealed by this survey as important factors. It was indicated that in certain cases differential diagnosis of Lept. icterohaemorrhagiae and Lept. canicola was impossible unless repeated serologic tests are accomplished. In another group of cases involving only Lept. canicola the exclusive role of the dog as a transmission factor was questioned.

A SYRINGE-TRANSMITTED EPIDEMIC OF INFECTIOUS HEPATITIS

With Observations Regarding the Incidence and Nature of Infectious Donors

RICHARD B. CAPPS, M.D.*
VICTOR SBOROV, M.D.
and
CHARLES S. SCHEIFFLEY, M.D
Chicago

The danger of accidentally transmitting disease from one person to another by means of a common hypodermic syringe has generally been looked on as remote. This is particularly true when dealing with apparently healthy persons. In fact, until recently, syphilis and malaria were the only common infections which were known to be readily transmitted in this manner. With the widespread and frequent use of syringes in the modern practice of medicine, the demonstration that another disease, virus hepatitis, may be so transmitted becomes a matter of considerable importance.

It has now been experimentally demonstrated that virus hepatitis, including both the infectious or epidemic and the homologous serum type, may be transmitted to human beings by the parenteral injection of infected serum.[1] As little as 0.01 cc. of serum has been sufficient to produce the disease.[2] The filterable agent is present in the blood during both the preicteric and the acute stage of the illness and, in the case of homologous serum hepatitis, during the incubation period.[3] Accidental transmission through transfusions of whole blood, plasma and convalescent serum and injections of biologicals to which serum has been added has been frequently reported.[4] Less widely appreciated in this country is the danger of transmission by means of unsterile syringes or needles. British workers have shown that this frequently occurs [5] and can be prevented by proper sterilization.[5b,f] Transmission may also occur during an ordinary venipuncture for the withdrawal of blood, as well as during parenteral injections, since Mendelssohn and Witts [6] have demonstrated that regurgitation of blood back into the vein usually occurs when the tourniquet is released. Finally, transmission by means of the "multiple dose per syringe" technic has been described.[7] In this method, which is commonly employed for the administration of such medicaments as vaccines, penicillin or antisyphilitic drugs to large groups, a small amount of serum is often unwittingly aspirated when the plunger is withdrawn to ascertain that the needle is not in a vein. In this manner the remaining material in the syringe may become infected.

Obviously the question of "carriers," or infectious donors of this disease, and the extent of their dissemination among the population is of fundamental importance in evaluating the danger of accidental parenteral transmission. During a special study of the problem of virus hepatitis conducted for the Surgeon General's Office by one of us (R. B. C.) at a United States Army General Hospital in this country, a syringe-transmitted epidemic of infectious hepatitis was encountered. A number of cases developed among men who had received tetanus toxoid on a certain day by the "multiple dose per syringe" technic. Since all the involved personnel who were available were studied, data regarding possible donors was obtained. We are making this report with this problem particularly in mind.

METHODS

Histories, physical examinations and the clinical portion of hepatic function tests were carried out in the clinic by a team of medical officers with special experience on the hepatitis wards. Patients with active hepatitis were admitted to the hospital and studied in detail.

The following laboratory procedures were employed. Retention of sulfobromophthalein sodium was determined at forty-five and sixty minutes after a dose of 5 mg. per kilogram. Previous control studies by ourselves and others [8] indicate that in this age group there should be no retention of dye even at forty-five minutes. For technical reasons we believe that 3 per cent and 2 per cent retention of dye at forty-five and sixty minutes respectively can be considered as doubtful and 4 per cent and 3 per cent as definitely abnormal. Serum bilirubin was determined spectrophotometrically, the modification of the Van den Bergh test described by Ducci and Watson being used.[9] Normal values according to Watson are 0.2 mg. per hundred cubic centimeters for the prompt direct (or one minute) reading of bilirubin and up to 0.8 mg. per hundred cubic centimeters for the total bilirubin. Ninety-seven per cent of our 35 normal controls gave values for both types of determination within this range. One case fell in the borderline range of 0.2 to 0.4 mg. per hundred cubic centimeters for the prompt direct reading. Urine urobilinogen was determined on a two hour specimen of urine by the quantitative method recently described by Watson, Schwartz, Sborov and Bertie.[10] Our control data indicate that the normal range originally proposed is probably too low. We feel that it is safer to take 1.0 to 1.5 total Ehrlich units as the borderline level and more than 1.5 total Ehrlich units as positive. Cholesterol esters were determined by Block's modification of Bloor's method.[11] All of our normal control determinations (15 cases) showed over 50 per cent esters, and 80 per cent of the controls showed over 55 per cent esters. Consequently, we have taken 50 to 55 per cent as borderline and less than 50 per cent as positive. Bilirubinuria was determined by the modified methylene blue test [12] and the "strip" test.[13] The cephalin cholesterol flocculation test was performed as described by Hanger.[14] It should be noted that our antigen was relatively insensitive, frequently giving negative results even during acute hepatitis with jaundice.

DESCRIPTION OF EPIDEMIC

One hundred and ten presumably healthy men, members of the detachment, received routine intramuscular injections in the arm of tetanus toxoid on Aug. 31, 1945. The material was administered from 10 cc. syringes containing ten doses each, and needles were changed between patients. A total of eleven syringes were required. Syringes were sterilized after being used for ten injections and before being refilled, while a freshly sterilized needle was employed for each patient. Sterilization was accomplished by means of a hot water sterilizer and was probably adequate, since enough equipment was available to allow for thirty minutes or more of immersion in boiling water.

Toward the end of September several cases of infectious hepatitis were recognized among the detachment, and inquiry revealed that in each case tetanus toxoid had been received on August 31. Consequently, all who had received toxoid on that date were called in for a history and a physical examination. Fifty-six men of the original 110 remained on the post, the others having been discharged or transferred elsewhere. Those with a history of acute symptoms or with abnormal physical findings compatible with infectious hepatitis were given a series of hepatic function tests. The examinations were done the second week of October, but unfortunately it was impossible to complete the laboratory part of the program until the first week of November. In consequence, abnormal findings in the cases of milder disease may have disappeared.

As indicated in table 1, history revealed that in 23 men symptoms developed characteristic of acute infectious hepatitis between September 15 and October 8. Specifically, the incubation period varied from twenty-one to thirty-eight days in 21 cases and was fifteen and sixteen days, respectively, in the other 2. Although the latter two intervals are unusually short, Havens has observed such incubation periods in artificially induced cases.[15] Two men gave a history of symptoms compatible with chronic hepatitis of six and nine months' duration, respectively, but neither had been sufficiently ill to report to sick call. The remaining 31 men denied the presence of symptoms during the previous two months.

TABLE 1.—*Occurrence of Acute Symptoms Consistent with Infectious Hepatitis Fifteen to Thirty-Eight Days After Injections of Toxoid*

	No. of Men
No recent symptoms	31
Chronic symptoms	2
Recent acute symptoms	23
Total men examined	56
Men that had left post	54
Total men receiving injections on August 31	110

RESULTS OF EXAMINATION OF INVOLVED PERSONNEL

The men in the group with acute symptoms gave a history of fatigue, indigestion especially to fatty foods, anorexia, flatulence and loose stools without real diarrhea. A few had nausea and vomiting, ache in the right upper quadrant, somnolence and urticaria. Fever was noted infrequently. In all cases symptoms persisted for at least ten days and usually longer. In a few instances aggravation from exercise was noted.[12b] One man (case 6) had dark urine and light stools.

The physical and laboratory observations in the group with acute symptoms are recorded in detail in table 2 Our evaluation of the significance of these observations is indicated by a division of cases into positive, questionable and negative or incomplete. In the "positive" group are placed all cases with either definite enlargement and tenderness of the liver, elevation of the retention of sulfobromophthalein sodium, increased serum bilirubin or multiple other abnormal findings. Cases in the "questionable" group all have evidence of hepatic dysfunction but less pronounced in degree. Findings in the last group are for the most part incomplete or negative. No laboratory tests at all were made in 3 of these cases.

All sulfobromophthalein sodium tests were done between October 24 and October 30 except for case 2, in which it was done on November 2, and case 6 on October 20. The Van den Bergh and other tests were performed between October 26 and November 9 except for case 10, in which they were done during the first two weeks of October. Clinical jaundice was observed only once (case 10). Likewise, bilirubinuria was found only in this 1 case, although a history of dark urine was not infrequently obtained. In the remaining patients, the disease must be classified as nonicteric or subclinical and therefore mild. Laboratory findings have frequently returned to normal in this type of case after three to six weeks.[16] This is particularly true of bilirubinuria and bilirubinemia, as well as the results of the cephalin cholesterol flocculation test. The significance of the negative results of the last test was further diminished by a relatively insensitive antigen. Finally, it should be noted that the subsequent disappearance of abnormal findings in many of our cases enhances their significance.

Unfortunately, it was impossible to make a similar set of observations on a control group due to lack of facilities. However, only 1 sporadic case of acute infectious hepatitis was recognized in the remainder of the detachment of approximately 700 men during the months of September and October, although the medical officers were alert for the disease. In view of the fact that 5 of our group of 23 men with acute symptoms reported to sick call voluntarily and were hospitalized, it appears extremely unlikely that the acute disease was epidemic in the rest of the detachment. It should further be noted that our laboratory procedures were individually con-

# There was aggravation of symptoms from exertion.

trolled, detachment personnel and patients being used as indicated in the section on methods. The figures so obtained were used to establish our normal values and so constitute a partial control.

There was no segregation of the group studied as compared with the rest of the detachment in regard to living quarters, duty assignments or mess. Since the toxoid injection was the only apparent common factor, it is evident that it must have had etiologic significance. In view of these facts it is not unlikely that all 23 men who experienced similar acute symptoms at an appropriate interval following presumed exposure actually had acute infectious hepatitis. However, even in an epidemic in which clearcut cases with jaundice are present it is best to require objective evidence of hepatic abnormality before making the diagnosis of hepatitis. On this basis there were 11 definite cases ("positive" group, table 3) with perhaps 6 more doubtful ones ("questionable" group, table 3).

TABLE 3.—*Summary of Physical and Laboratory Findings in Men in Whom Acute Symptoms Developed in Fifteen to Thirty-Eight Days After Injections* *

Physical and Laboratory Findings	Number of Cases	Percentage of Total Examined
Definitely diagnostic of hepatitis............	11	19.6
Questionably diagnostic of hepatitis........	6	10.7
Negative or incomplete........................	6	10.7
Total men with acute symptoms.........	23	41.0

* Complete findings are recorded in table 2.

Examination of the 2 patients with chronic symptoms revealed that both had physical and laboratory evidence of hepatic disease without jaundice (table 2). One gave a history of having accidently swallowed serum from a patient suspected of infectious hepatitis while working as a laboratory technician late in July. An exacerbation of his symptoms occurred on September 10. The nature of the hepatic disease in this case is not clear. It may have been a chronic infectious hepatitis with a superimposed acute infection possibly from another strain, or it may have been either one alone. In any case he did not contract his disease on August 31 but on the contrary was possibly infectious at that time and may have served as one of the donors.

Physical examination of the 31 men without symptoms revealed 3 with enlarged livers, one being slightly tender. Unfortunately it was not feasible to do further tests on any but these 3. As shown in table 2 (cases 1a, 2a, and 3a under "asymptomatic") 1 had a definitely elevated retention of sulfobromophthalein sodium and 1 an increased excretion of urobilinogen. Whether these cases represent asymptomatic acute infectious hepatitis, chronic asymptomatic (inactive) infectious hepatitis or some other type of hepatic disease cannot be stated. Possibly some were infectious. If all 31 asymptomatic men had been given hepatic function tests, probably more cases of this sort would have been discovered.

THE INCIDENCE OF DONORS OR "CARRIERS"

Eleven of the 56 men who were examined had contracted acute infectious hepatitis, an incidence of 20 per cent. This makes it probable that of the original 110 men given injections, approximately 22 contracted the disease. Since a maximum of 9 men could have been infected from a single syringe, assuming in each instance that the first person given an injection was a donor, it follows that there must have been at least three contaminated syringes and 3 infectious donors. However, it is more likely that on the average a syringe would become contaminated when half empty, so that only 4 or 5 men would be exposed per contaminated syringe. If the more conservative figure is employed, there would have been five such syringes or 5 infectious donors, making an incidence of 5 per cent in the original group (table 4).

TABLE 4.—*Showing Derivation of the Probable Incidence of Infected Donors in Original Group*

Total number of men receiving injections August 31..................	110
Percentage contracting acute infectious hepatitis........................	20
Total number of original group contracting hepatitis.................	22
Number of infected syringes (average of 5 men infected per syringe)	5
Percentage of "donors" in original group..............................	5

Although these figures are too small to justify accurate statistical analysis, most of the potential errors would lead to a higher incidence of donors. Thus, as previously pointed out, the number of men contracting acute hepatitis was probably greater than 20 per cent. Secondly, it is unlikely that serum would be aspirated from every infectious person. And finally, 25 to 50 per cent of persons given injections of infectious material do not contract the disease, presumably because of immunity.[17] Consequently, it can be concluded that the incidence of infectious donors or carriers in the original group was probably at least 5 per cent and possibly much higher.

There is, of course, no way of ascertaining which men acted as infectious donors. Information is not available regarding the 54 men who had left the post except that there was no record of any of these having reported to sick call. One who left about the middle of September may have been jaundiced. He was observed by a medical officer during a casual meeting at the time of his departure. The only conclusion to be drawn is that the infectious donors were either asymptomatic or not sufficiently ill voluntarily to report to sick call. It seems probable that some of them fell into the first group and were apparently healthy. Whether such donors are true carriers or represent asymptomatic cases of acute or chronic infectious hepatitis recognizable only by laboratory procedures cannot be determined from this data.

COMMENT

This study demonstrates in a striking manner the danger of extensive dissemination of the virus of infectious hepatitis through the use of the "multiple dose per syringe" technic. That this was the actual mode of transmission cannot, of course, be absolutely proved, but it appears to be the only reasonable explanation. Sterilization of needles and syringes before and after use was apparently adequate. Furthermore, in the absence of gross carelessness, improper sterilization could hardly account for the large number of cases observed. In evaluating the high incidence of induced infection, 20 per cent, it is well to remember that the cases of mild nonicteric infectious hepatitis are difficult to diagnose and are usually not recognized except during an epidemic when the date of exposure is known. These persons often fail to consult a physician because symptoms are not sufficiently severe. Thus in our group only 1 man had clinical jaundice and probably not over one third would have voluntarily reported to sick call. It is recognized that some may differ with our criteria for making the diagnosis of acute hepatitis without jaundice. Although we agree that it is a particularly difficult diagnosis in sporadic cases, in an epidemic of this sort when the date of exposure is known we believe that it can be made with reasonable assurance.

---

[17] (a) Havens.[15] (b) Neefe, J. R.: Recent Advances in the Knowledge of "Virus Hepatitis," M. Clin. North America 30: 1407, 1946.

Of unusual interest is the rather surprising inference that approximately 5 per cent and possibly more of an unselected group of 110 men carried the virus of infectious hepatitis in their blood. Only 20 per cent of those questioned had been overseas and none had been in the Mediterranean theater, where the incidence of hepatitis was greatest. No explanation for this high figure is available.

Judging from the short incubation period, this epidemic was one of so-called epidemic hepatitis. It is of interest that Sawyer and co-workers [4h] in a careful study of the homologous serum epidemic of 1942 in the army arrived at a similar figure for the incidence of carriers. They suggested that 6 per cent and probably considerably more of the population carry this virus in their blood. This figure was based on the assumption that forty-seven lots of yellow fever vaccine out of a total of one hundred and seventeen studied were infected or icterogenic. To each lot was added pooled plasma from known donors. Nine hundred and seventy different donors were used, affording a fair sample of the local population. However, there is reason to suspect that more than forty-seven lots of vaccine were icterogenic and that a 6 per cent incidence of carriers is consequently too low. Thus the incidence of hepatitis from each lot of vaccine was determined by questionnaire and undoubtedly included only hospitalized patients. A careful study of unselected samples of both hospitalized and ambulatory recipients of two lots of vaccine at Fort Custer by one of us (R. B. C.) in association with others [18] gave startlingly different results, as shown in table 5. Lot 368 was generally admitted to be icterogenic but lot 382 was classified as nonicterogenic by Sawyer. Similar studies involving four other lots of vaccine classified as nonicterogenic were made at Fort Custer. The groups were too small for statistical analysis, but the trend was the same as for lot 382. Most of the cases occurring after use of these lots were mild, either nonicteric or with only a slight, transitory jaundice and would never have been recognized unless unselected samples of ambulatory recipients had been studied. From this data we can conclude that probably considerably more than forty-seven lots contained the virus and that the incidence of carriers was correspondingly higher than 6 per cent.

TABLE 5.—*Incidence of Hepatitis Per Thousand Men Given Injections from Two Different Lots of Yellow Fever Vaccine*

Vaccine Lot No.	Sawyer et Al.[4h]	Custer [18]	Size of Custer Sample
368	67.59	371.0	1,857
382	0.33	220.0	146

Finally, the wide dissemination of this virus among the population is evidenced by the frequency of catarrhal jaundice, which is probably identical with what is now called infectious or epidemic hepatitis. It is generally stated that approximately 5 per cent of adults give a history of this disease. If we also include the cases of unrecognized nonicteric disease, the total incidence would probably be at least 10 to 15 per cent and possibly considerably higher.

The few experimental observations available on human volunteers have failed to demonstrate persistence of the virus in the blood stream after the first month of illness,[19] although Neefe and co-workers have recently shown that the virus may persist in the feces and liver.[19c] However, it is difficult to explain the evidence presented in this paper except by the assumption that some persons become "carriers" of the virus, which is present in their blood. Since there is no way of determining which of our patients actually served as infectious donors, definite conclusions regarding the nature of such carriers cannot be reached. It can, however, be stated that only 2 of the potential carriers had symptoms and that in neither case were the symptoms sufficiently severe to require professional advice. Furthermore, none had a history of jaundice. Thus, for practical purposes, carriers may be apparently healthy persons without a recognizable past history of hepatic disease. Presumably their original infection was of the mild nonicteric type which is probably the most common. Whether persons with chronic symptomatic (or active) hepatitis or with asymptomatic evidence of hepatic disease (inactive hepatitis) are more likely to be carriers than those without any residuals is not known.

Sawyer and his colleagues [4h] arrived at essentially the same conclusions in their study of the plasma donors responsible for the homologous serum epidemic of 1942. In the case of many of the lots of icterogenic vaccine there were no donors with a history of jaundice, while in others there were donors with a history of jaundice from one to twenty years previously. In most cases donors were apparently well at the time of the blood letting.

The foregoing considerations have an important bearing on the potential danger of accidently transmitting this disease by parenteral inoculation. Not only does the available evidence indicate a relatively high incidence of carriers in the population but the nature of the latter is such that detection is for practical purposes impossible. Thus in the use of blood and blood products a calculated risk must be assumed. Syringe and needle technics should be carefully checked and revised, so that proper sterilization is accomplished. Consideration should also be given to the technic of finger puncture for blood counts. Although cases produced in this way have not yet been observed, there can be no doubt that the usual methods do not provide satisfactory sterilization of needles or lancets.

These observations reemphasize the frequency of acute hepatitis without jaundice. In this group 91 per cent of the cases fell into this category. In a previous study of the homologous serum epidemic of 1942 we reported that 70 per cent of 1,958 cases were without jaundice.[12b] Among the 32 cases studied from vaccine lot 382 (table 5), 90 per cent were nonicteric. On the other hand, in an epidemic studied by Neefe [17b] in only 26 per cent of 342 cases did overt jaundice fail to develop. Such variations are to be expected. Nevertheless, it is obvious that the nonicteric form of the disease is common.

Bennet, Medical Corps, Major A. E. De Groat, Medical Corps, Major H. A. Davenport, Medical Corps, and Major F. W. Fitz, Medical Corps.

[19] (*a*) Havens.[2] (*b*) Neefe.[17b] (*c*) Neefe, J. R.; Stokes, J. Jr.; Garber, R. S., and Gellis, S. S.: Studies on the Relationship of Hepatitis Virus to Persistent Symptoms, Disability and Hepatic Disturbance Following Acute Infectious Hepatitis, J. Clin. Investigation **26:** 329, 1947.

It is noteworthy that 4 of the 10 persons with nonicteric disease were still sick three months after onset and could be classified as entering the chronic stage.[8b] This lends support to the concept proposed by Bloomfield in 1938 [20] and previously supported by ourselves [8b] that acute nonicteric hepatitis may lead to chronic hepatitis and perhaps in some cases to cirrhosis. This possibility is undoubtedly enhanced by lack of treatment resulting from failure to make the diagnosis. The importance of proper recognition is obvious.

CONCLUSIONS

An outbreak of infectious hepatitis apparently resulting from the use of the "multiple dose per syringe" technic for the administration of tetanus toxoid is reported. At least 20 per cent of the recipients of the toxoid contracted acute infectious hepatitis. It is estimated that probably 5 per cent of the original group must have carried the virus in their blood. Most of these were apparently asymptomatic and none were sufficiently ill to consult a physician voluntarily. The epidemiologic import of these figures is discussed, particularly as involves transmission by way of plasma, blood and syringe.

EPITHELIAL METAPLASIA OF THE URINARY TRACT

FRANK S. PATCH, M.D.
Montreal, Canada

The finding of tissue cells of another type than those normally found in an organ of the body is always intriguing, and the explanation of such an occurrence presents many difficulties. It is not strange that differences of opinion have arisen as to the exact mechanism by which such a metamorphosis of tissue cells has been produced.

Such changes are found not infrequently in the epithelium of the urinary tract, where they present an interesting urologic study. In this discussion I am confining my attention to the changes occurring in the renal pelvis, the ureters and the bladder. Although the epithelium of these organs possesses a different derivation embryologically, that of the ureter and pelvis being mesodermal and that of the bladder partly entodermal and partly mesodermal, they are all lined with transitional cell epithelium, and, except perhaps in the immediate neighborhood of the bladder outlet, true glands are not normally present.

Metamorphosis of the epithelium in these organs is of two distinct types: 1. The substitution for the normal transitional cell epithelium of a stratified keratinizing epithelium and the development of leukoplakia and, by what may be regarded as a further extension of the process, squamous cell carcinoma. In this group, the epithelial change is toward an epidermal type of cell. 2. The appearance in the mucosa of glandular formations, with secretory properties, the so-called cystitis glandularis. In a striking parallelism to the preceding group, there develops a mucin-secreting adenocarcinoma. In this group, the change is toward an entodermal type in which an epithelium is found, resembling that of the large bowel.

Though various explanations have been advanced to explain these processes, two theories are most widely held at the present time: (1) that the changes are due to embryonic cell inclusions from contiguous structures; particularly is this a point of conflict of opinion in the matter of the glandular formations; (2) that the changes are due to metaplasia.

It is desirable that the two groups be considered separately, even if there are many instances of significant parallelism in their respective courses. In some conditions in which they are commonly encountered, notably in exstrophy of the bladder and in the bladders of sufferers from schistosomiasis, they are found in intimate association.

The literature is rather voluminous, and I shall not attempt to cover it. At times it is even repetitious, a fault of which I myself may on this occasion be found guilty.

It is necessary to consider, on the one hand, leukoplakia and squamous cell carcinoma and, on the other hand, cystitis glandularis and the mucin-secreting adenocarcinoma.

LEUKOPLAKIA AND SQUAMOUS CELL CARCINOMA

Since 1900, up to which time few cases of leukoplakia and squamous cell carcinoma had been reported, there has been a steady increase in the number of case reports appearing in the literature, so much so that neither may be regarded as an unduly rare occurrence. It is perhaps reasonable that leukoplakia is noted less frequently than the more serious squamous cell carcinoma. Both conditions are met with most often in the bladder, less so in the renal pelvis and least of all in the ureters. They may even be observed in multiple foci.

There is not the same tendency to ascribe the presence of leukoplakia to embryonic cell inclusions as in the case of the glandular formations. Though some authors, in particular Hinman and Gibson,[1] have explained its occurrence as the result of an effort on the part of the epithelium to exercise its inherent power of adaptation to environment in the form of protective cornification, most authors, including the pathologists, have agreed that leukoplakia is metaplasic in origin.

Leukoplakia is usually associated with long-standing irritation and inflammation. It also follows, as has been shown by Wolbach and Rowe [2] experimentally the deprivation of fat-soluble vitamin A in laboratory animals. They showed that many different types of epithelium were replaced by stratified keratinizing epithelium, not only in the genitourinary tract, but also in the gallbladder, the trachea and the eyes. In their article, the autopsy of a case occurring in a human being was reported, in which the same epithelial changes were observed. In a later article, the same authors showed that no matter what type of epithelium was involved, in spite of origin from any of the three embryonic layers, in the repair following restoration of the diet, each epithelium was replaced by the kind

normal to the location. They stated their conviction that the occurrence of leukoplakia is due to metaplasia. They made a most significant observation when they stated that "the behavior of the cells in a few of the animals . . . suggests the acquisition of neoplastic properties."

Most authors look on leukoplakia as a precursor of squamous cell carcinoma and believe that the cancer is an extension of the process. Against this, it has been urged that not all cancers are preceded by leukoplakia. Further than this is the fact that in only a relatively small number of cases have leukoplakia and squamous cell carcinoma been found in association.

In 1929 I collected 13 cases in which the two conditions were associated.[3] Since that time eight other case reports have been made, 4 by Goebel,[4] a second by Scholl,[5] and 1 each by Potts,[6] Kifman [7] and Aschner.[8] Rabson in 1936,[9] collected 18 instances of their occurrence in the bladder.

The report of Goebel deserved more than a passing reference. This was based on a study of tumors of the bladder in schistosomiasis. He found that in 4.3 per cent of sufferers from this disease cancers of the bladder developed. Schrumpf-Pierron [10] stated that, although the incidence of malignant tumors in Egypt is ten times less than in Europe and on this continent, the incidence of cancers of the bladder is much higher relatively. About 13 per cent of malignant disease in Egypt is due to schistosomiasis, mainly in the bladder.

The infestation of the bladder with Schistosoma haematobium is accompanied by intense irritation and produces a condition most favorable for metaplasic changes. Goebel reported 20 cancers of the bladder of which 11 were squamous cell carcinoma. All of these cases showed associated epidermoid metaplasia, and in 4 there were definite leukoplakias. Incidentally, there was 1 case of glandular cancer in his series.

The fact that relatively so few instances of the association of the two conditions have been found has been cited against the belief of a causal relationship. However, several authors have demonstrated intermediate stages between the two processes. Hinman, Kutzman and Gibson [11] observed, in sections of leukoplakia of the renal pelvis, evidences of what they thought must be regarded as definitely precancerous lesions. Hallé,[12] in a case in which the leukoplakia and squamous cell carcinoma were associated, found definite intermediate steps between the two conditions. We ourselves were able to give some confirmation to this finding. In our reported case of associated leukoplakia and squamous cell carcinoma of the renal pelvis and bladder, my colleague, the late Dr. Rhea, by taking serial sections, was able to demonstrate evidences of a transition between the two conditions.[13] These, in his opinion, if not definitely malignant, were certainly precancerous.

It may be that the question is not one of paramount importance. It is not necessary to assume that squamous cell carcinoma must be preceded by leukoplakia. Rabson [9] suggested that it is probable that squamous cell carcinoma in the bladder is caused by the same factors responsible for the leukoplakia, and that the carcinoma represents a "further distortion and exaggeration of the metaplasic process." In these cases, there is no intermediate benign stage, but rather an acceleration of the metaplasic process and an uninterrupted development of the malignancy. The condition, in other words, is malignant from the outset.

CYSTITIS GLANDULARIS AND MUCIN-SECRETING ADENOCARCINOMAS

The occurrence in the bladder of glandular formations possessing the faculty of secreting mucin has given rise to much discussion, and diametrically opposed views are held as to their origin. Is the process a metaplasic one, the result of chronic irritation or inflammation, or is it the result of embryonic inclusions of germinal cells of the lower intestinal tract? In view of the partial derivation of the bladder epithelium from entodermal tissues and as the bladder normally is devoid of glands, this latter assumption was not entirely unnatural. Probably the earliest reports of what is now known as cystitis glandularis were made on the exstrophied bladder, and such an assumption must have appeared logical to its first observers. However, in recent years, several facts have been revealed which makes the metaplasic theory a much more plausible one.

There are the observations of Enderlen [14] and Formiggini.[15] Both authors noted that the mucosa of the exstrophied bladder at birth was normal and that it was lined with normal transitional cell epithelium. There was a complete absence of glandular formations. The leukoplakia and cystitis glandularis which are such prominent features of the exstrophied bladder must therefore be regarded as postnatal acquisitions.

Furthermore, the occurrence of glandular formations in the renal pelvis and ureter (pyelitis and ureteritis glandularis) has been reported, notably by Brütt [16] and Paschkis.[17] The occurrence of mucin-secreting adenocarcinomas in the renal pelvis and in the ureter has also been reported. As the epithelium in these organs is derived from mesodermal tissues, the theory of entodermal inclusion loses much of its force.

Stoerk and Zuckerkandl [18] were the first to suggest that the glandular formations developed from the epithelial cell nests of von Limbeck and von Brünn, as the result of chronic inflammation. They were convinced that the process was definitely a secretory one and not a degenerative one. In the epithelial cell nest a cavity develops, gradually becoming lined with characteristic tall cells, with basally placed nuclei. The end result is a gland which secretes mucin, a condition to which they gave the name of cystitis glandularis. They stated their conviction that the theory of the developmental origin of cystitis glandularis had lost every basis of fact.

In the same article, these authors pointed out that it might well be expected that epithelium which had undergone such a deviation from its normal character and had developed the habit of proliferation would go further and acquire malignant properties. In support of this, they reported a case of mucinous adenocarcinoma which had developed in an exstrophied bladder.

Furthermore, the changes which I am describing have been produced experimentally. Giani,[19] in an experiment for another purpose, introduced foreign bodies into the bladder of a rabbit and was surprised to observe the development of epithelial cell nests and cystitis cystica.

At this point, it seems desirable to make a brief reference to the not infrequent finding of cystitis cystica and the corresponding conditions in the renal pelvis and ureter. It is my opinion that these conditions represent one aspect of the process, which ordinarily leads to the development of active glandular formations. If the stimulus which initiated the process of adaptation should become inert, the process may be retarded and the gland epithelium may cease to function, or perhaps, overdistended by their own secretions, the epithelial cells become flattened and atrophied, and an impotent cyst remains. In other words, the cystic formations may be regarded as mere by-products of the process.

Most textbooks on pathology and urology speak of adenocarcinomas of the urinary tract as being exceedingly rare. Yet when one reviews the literature more closely one finds a surprising number of reports.

1. *Renal Pelvis.*—Four cases in the renal pelvis have been reported, those of Paschkis, Grohé,[20] Plaut [21] and Ackerman.[22]

2. *Ureter.*—Seven cases in the ureter have been reported, by Metcalf and Safford,[23] Kneise,[24] and 5 cases cited by Scott [25] (Cross, Einzig, Harrah, Mayock and Baurys, and Papin).

3. *Bladder.*—Here, it is not easy to compile statistics partly owing to the confusion which exists in describing these tumors and the great variation which is found in their nomenclature. Further, frequently no reference is made to the question of secretion of mucin.

In any event, the tumor is relatively a rare one. Scholl [5] found 5 in 333 tumors of the bladder observed at the Mayo Clinic in ten years. One of these occurred in an exstrophied bladder. Gayet [26] found 21 cases of cancer in exstrophied bladders, 16 being adenocarcinomas and 2 of the squamous cell variety. In the Montreal General Hospital only 3 cases of mucinous adenocarcinomas have been observed since 1910.

Some confusion has arisen in connection with tumors of the bladder vault, which some authors claim are in reality urachal tumors presenting in the bladder. Begg [27] (1936) reported 5 colloid adenocarcinomas and 2 adenocarcinomas (not colloid) which he placed in this category. In addition to these, he found 14 colloid adenocarcinomas in the urachus and 1 adenocarcinoma (not colloid). Hayes and Segal [28] (1945) in reporting a case stated that they had found an additional 25 cases in the literature. Higgins [29] has reported a further case.

Without making an exhaustive and critical study of these cases, it would appear that some cases at least have been included as urachal tumors which were regarded by the authors as being definitely of vesical origin.

Doubtless some tumors in the bladder vault originate in urachal epithelium. It is not proved, however, that all of them do. Two of the 3 cases reported by us [30] were situated in this area of the bladder. That they were of vesical origin was proved by intraperitoneal observation. In our third case it was in the neighborhood of a ureteral orifice.

Begg,[27] who has shown a special interest in urachal tumors, admitted that the urachus is a modified upper end of the fetal bladder and that its epithelium is essentially similar to that of the bladder. He stated:

> The urachal cells retain all the potentialities of primitive cloacal cells and are able to bring them at any period of life to fruition. Complete, but ill-regulated development toward glandular or transitional epithelium respectively may be observed. This development may overstep all bounds and give rise to colloid adeno-carcinoma on the one hand or squamous cell carcinoma on the other. As a rule, the full impulse given by the entodermal origin of the cells predominates, and the formations commonly seen pass through the stages of simple adenoma and adeno-carcinoma to reach finally the fully-formed colloid cancer of the rectal type.

It seems, however, that the question of urachal origin is not of paramount importance, when one considers that the urachal epithelium is similar to that of the bladder. The theory that an adenocarcinoma arising in the urachus is due to embryonic cell inclusions is just as open to argument as in the case of one arising in the bladder, and the metaplasic hypothesis is equally plausible.

It is interesting to compare the incidence of cancer in the exstrophied bladder, and in the bladder infested with the S. haematobium. In both cases an intense and long-contained irritation is present. In both there is an increased incidence of malignant growths of both types.

In the exstrophied bladder, as has been pointed out, mucinous adenocarcinomas predominate, possibly the result of an effort of the epithelium to adapt itself to its environment and to prevent, by a profuse secretion of mucus, an excessive desiccation of the exposed vesical epithelium. In the bladder affected by schistosomiasis, however, the squamous cell carcinomas predominate, in almost inverse ratio. This may be regarded as an attempt of the vesical epithelium to adapt itself to its irritating environment by the development of a protective cornification.

In both conditions the vesical epithelium strives to adapt itself to its environment by utilizing both methods. So in the exstrophied bladder, leukoplakia is often found in close association with cystitis glandularis, while in the bladder affected by schistomosiasis the reverse obtains.

Except in these two conditions, it is not easy to form any conclusions on the association of cystitis glandularis and adenocarcinoma. Often the diagnosis is based on the sole examination of a surgical specimen. Autopsies which would permit the fullest examination of the

urinary tract are not always secured. None the less, many authors have noted the finding of cystitis glandularis in close association with the carcinoma.

In view of the frequent occurrence of cystitis glandularis and its comparable conditions in the renal pelvis and ureter, that so few cases of adenocarcinoma develop is a fact not easy to explain. It may be reasonable to infer that in many cases the original inciting factor ceases to be active and that recovery follows. In this respect the disappearance of the leukoplakia in the previously cited experiments of Wolbach and Rowe is most significant.

It may be, as was suggested in the discussion of the relationship between leukoplakia and squamous cell carcinoma, that an adenocarcinoma may result from an acceleration of the metaplasic process, stimulated by the same conditions which produced in more leisurely fashion the benign glandular formations.

In this connection, it may be noted that clinical observations have shown that the cystic and glandular formations in the bladder, at least, may disappear when the inciting irritation or infection has been eradicated by appropriate measures.

Though no clinical observations on the disappearance of leukoplakia in the human being are found, the experimental work of Wolbach and Rowe has shown that this does occur in laboratory animals. In animals in which leukoplakia had developed when they were given a diet deficient in vitamin A, the leukoplakia completely disappeared once the animals were restored to a normal diet.

Epithelial cells of the urinary tract possess latent potentialities of proliferation which, even on minimal irritation, may be followed by further, even unrestrained, growth. This change in the character of the cell may cease to be active or may even be reversed.

In view of the many doubts which still exist regarding the character of the changes which I have been discussing and which I regard as metaplasic, it is highly desirable that every opportunity be used to make complete and thorough examinations in every case in which they are observed.

CONCLUSIONS

Leukoplakia of the renal pelvis, ureters and bladder, and cystitis (pyelitis and ureteritis) glandularis are the result of epithelial metaplasia in response to a call for altered function, or at least as the result of altered environment. These metaplasias are commonly associated with chronic, long-standing irritation or infection.

Leukoplakia may follow vitamin A deficiency. In this condition it is not secondary to an infection.

The extent and intensity of the metaplasic process is in direct relation to the intensity and duration of the inciting factors.

Both conditions are potentially malignant. They may develop a malignant character by a further extension of the metaplasic process into squamous cell carcinoma and mucinous adenocarcinoma respectively.

Both types of cancer may develop, primarily, by an acceleration or intensification of the metaplasic process. It is possible that the epithelial changes may be reversible.

Clinical Notes, Suggestions and New Instruments

PULMONARY AND CEREBRAL FAT EMBOLISM FOLLOWING INTRAVENOUS ADMINISTRATION OF ETHER THERAPEUTICALLY

LOUIS LICHTENSTEIN, M.D.
and
SYDNEY SEWALL, M.D.
New York

The administration of ether intravenously for the nonsurgical treatment of impending ischemic gangrene has recently been advocated[1] as a safe procedure that promotes collateral circulation and affords relief from severe pain. Specifically, the advocates of this method of treatment for peripheral vascular disease recommend the daily infusion of 2½ per cent ether in a liter of isotonic solution of sodium chloride or (for hypertensive patients) dextrose for twelve consecutive days, followed after two days rest by a second course. Some of the complications encountered in carrying out this regimen have already been pointed out by Wirtschafter and Widmann.[2] The purpose of this report is to direct attention to another serious complication. In the first case in which the method indicated was employed at this hospital,[3] a fatality ensued during the course of treatment, which autopsy showed to have resulted from fat embolism. Inasmuch as the therapeutic regimen in question is likely to be given a rather wide clinical trial, it seems timely to emphasize, without prejudice to whatever therapeutic efficacy it may possess, that the intravenous administration of ether may be potentially dangerous.

REPORT OF CASE

History.—The patient was a moderately obese, hypertensive Negress, 75 years of age, who three months previously had had her left fifth toe amputated because of infection, Staphylococcus aureus having been obtained on culture. At the time, the dorsalis pedis artery could not be palpated, nor did oscillometric readings show any evidence of pulsation of the vessels of the calf on either side. The blood pressure was 240 systolic and 130 diastolic. The Kahn and Kline reactions were negative. Two weeks after the operation the wound broke down and examination showed an ulcerated, infected area on the dorsum of the amputation stump, as well as some swelling of the foot. Inasmuch as the conventional conservative methods had not proved efficacious and the patient declined further surgical intervention, it was decided to institute intravenous ether therapy, following precisely the method advocated by Katz.[1] During the course of treatment, the wound did become smaller and better demarcated and there was some subjective improvement, manifested chiefly in diminution of pain in the foot. During the course of the fifteenth infusion, however, after the latter had been going for one and three-fourths hours, the patient had a shaking chill and a temperature of 104 F., associated with substernal pain, nausea and vomiting. It was noted also that the blood pressure had dropped sharply to 110 systolic and that the pulse rate had risen to 120. The respiratory rate subsequently rose to 50 and the pulse to 150, the latter being shallow and thready. During the following day, the patient complained of respiratory difficulty even while in an oxygen tent, and in spite of supportive measures she died about thirty-five hours after the onset of untoward symptoms.

Postmortem Examination.—The significant observations only will be indicated. At the site of the amputation there was a small granulating wound, about 1 cm. in diameter, through which a spicule of bone from the head of the metatarsal bone protruded. The surrounding soft parts of the stump, however, showed no evidence of recent infection. As for the viscera, the heart was appreciably hypertrophied, reflecting the hyper-

[3] On the Orthopedic Service of Dr. Harry D. Sonnenschein.

tension, and showed patches of old myocardial fibrosis in the apical region and posterior wall of the left ventricle. There was severe coronary sclerosis, with focal narrowing of all the major branches but no indication of recent thrombosis. The lungs were voluminous and somewhat emphysematous, and on section presented dark-red moist congested surfaces, without evidence of bronchopneumonia. The liver parenchyma was strikingly soft and friable. The spleen was small and firm, and not remarkable, showing neither infarction nor fibrosis. The kidneys showed arteriosclerotic scarring, with slight reduction in size and evidence of congestion and parenchymatous degeneration. The stomach was dilated and contained about a liter of fluid material. The surface of the brain was congested, and serial section showed it to be peculiarly soft and congested throughout, although no significant focal lesions were discernible. From the gross findings alone, the cause of death was not clear, and the fatality was ascribed tentatively to hepatic damage, or possibly to cerebral injury.

Microscopic examination revealed a number of additional abnormalities that shed light on what had apparently happened in this case. Sections of the kidneys showed tremendously dilated, empty glomerular capillaries—a finding that prompted Dr. A. R. Rich, whom we consulted, astutely to suggest the possibility of fat embolism. The presence of fat globules within the glomerular tufts could not be demonstrated (although they may have been dissolved in the course of storage of the tissue blocks in alcohol). However, frozen sections of the lungs stained with sudan IV showed embolic occlusion by neutral fat of many of the alveolar capillaries and smaller pulmonary artery branches. The brain had not been preserved so that we were unable to do frozen sections in a search for fat emboli in the cerebral vessels. However, sections of the paraffin blocks showed congestion, focal demyelinization of the white matter, especially around blood vessels, and beginning reactive gliosis—findings resembling those described by Wertham and co-workers,[4] Groskloss,[5] Warren[6] and others in cases of

COMMENT

That fat embolism may develop following fractures, especially after surgical manipulation, is a commonplace observation.[7] The experience of the late war has also brought the full realization that fat embolism is a rather common and important cause of death after traumatic injuries in general, even without fracture of one or more bones.[8] Occasionally it may even be a consequence of severe burns. The explanation usually advanced in such cases is that fat particles mobilized from traumatized fatty bone marrow or other fat depots gain entry into the venous circulation, only to be trapped in the capillary bed of the lungs, and frequently of the brain, kidney and other organs as well. However, fat embolism is known to develop also in the absence of injury to fatty tissue, having been observed, for example, as a spontaneous phenomenon in cases of sickle cell anemia[9] and (rarely) in a variety of conditions characterized by lipemia.[7] Clearly, the explanation commonly invoked to account for fat embolism does not apply to such cases, and one must consider certain other possibilities. Thus, the source of the embolized fat globules may conceivably be the lipid envelope of erythrocytes in the blood, as Angrist[4] has cogently suggested in relation to fat embolism complicating sickle cell anemia. According to Leathes and Raper[10] the lipid content cerebral fat embolism. It should be mentioned also that the red cells appeared sickled in many places, but there were no changes in the spleen and other organs to indicate that sickle cell anemia had been present.

of the red corpuscles is actually greater than that of the plasma, and is apparently labile, since its amount and composition change in the course of fat metabolism. Still another potential source of embolized fat is the emulsified fat in the blood plasma, and, indeed, the latter may well have played a role in the development of fat embolism in our case. In this connection, it is pertinent to cite the observations of Lehman and Moore[11] that fat emulsions can be broken up by ether and that dogs to whom ether is administered intravenously show significant fat embolism, the extent of fat embolism being enhanced by alimentary lipemia. Incidentally, in the case that we are reporting, the ether infusion that proved fatal was started about two hours after lunch, at which time alimentary lipemia might be expected to be at or near its peak.

The hazard of fat embolism is also of concern to anesthetists who occasionally employ ether intravenously, although the method does not appear to be in general favor. Fatalities have undoubtedly occurred after the intravenous use of ether as an anesthetic,[12] but we have been unable to find any reports in which the outcome was ascribed to fat embolism, although it is altogether possible that the latter was overlooked. Instances of fatal fat embolism, however, have been reported after anesthesia with chloroform[7] and cyclopropane,[13] which are, of course, also fat solvents.

In administering ether as a therapeutic agent, one must consider its effect on the liver also, in view of the accumulated evidence that ether may produce alterations in hepatic function, as well as anatomic evidences of injury to hepatic cells. Also, in view of the finding by Wirtschafter and Widmann[2] of gross hematuria and urinary casts in a number of patients so treated, one must take cognizance of possible alterations in renal function as well. Indeed, if the ether infusion method is to be employed for the treatment of peripheral vascular disease, it seems but a reasonable precaution to require that the status of hepatic and renal function be determined before and also at frequent intervals during the period of treatment and that further administration of ether be promptly discontinued if evidence of functional impairment be found.

SUMMARY

In a case in which the intravenous administration of ether was employed for the relief of peripheral vascular disease, a fatality ensued which autopsy showed to have resulted from pulmonary fat embolism. There were also microscopic changes in the brain indicative of cerebral fat embolism. Some of the implications of this experience are discussed. Attention is also directed to the necessity for safeguarding against irreparable hepatic and renal injury by ether administered intravenously.

Epidemics Traced to Cheese.—A summary of the data shows that during this time (since 1883) there has been a total of fifty-nine epidemics with 2,904 cases of disease and 117 deaths. There is every reason to believe that this represents only a fraction of the total. After the epidemics reported by Baker in Michigan during 1883-1884 no epidemics were recorded until 1893, after which there was a lapse of twenty-one years before another epidemic was reported. Thereafter, only an occasional epidemic due to cheese was reported until 1932, when the big epidemic occurred in Quebec, with 627 cases and 57 deaths. This epidemic seems to have made public health official conscious of the fact that cheese may be an important vehicle for the transmission of disease, and from that time on we find one or more epidemics reported each year except in 1933. From 1935 to 1945 forty epidemics were reported involving 1,741 cases and 47 deaths, which is over twice as many epidemics as the nineteen which were reported in the previous forty-two years. Such figures lead one to suspect strongly that during this time cheese had been overlooked as a source of disease. —Fabian, F. W.: Cheese and Its Relation to Disease, *Am. J. Pub. Health*, August 1947.

AUSTIN SMITH, M.D., *Secretary.*

OXIDIZED CELLULOSE.—Hemopak-Johnson & Johnson.—Absorbable cotton or gauze.—Cellulosic acid.—$(C_6H_8O_6)$.—M. W. n(176.12). Oxidized cellulose is prepared by the nitrogen dioxide oxidation of surgical gauze or cotton. Cellulosic acid is a polyanhydroglucuronic acid having a minimal carboxyl content of 16 per cent, a nitrogen content not in excess of 0.5 per cent derived from the nitrogen dioxide used in its preparation, and a formaldehyde content not in excess of 0.5 per cent derived from the formaldehyde used in its sterilization.

Actions and Uses.—Oxidized cellulose, a specially treated form of surgical gauze or cotton, exerts an unusual hemostatic effect and possesses the property of absorbability when buried in the tissues. Its hemostatic action is dependent on the formation of an artificial clot by cellulosic acid, which has a pronounced affinity for hemoglobin but does not enter per se into the physiologic mechanism of clotting. Absorbability depends on the size of the implant used, the adequacy of the blood supply to the area and the degree of chemical degradation of the material. Absorption of oxidized cellulose ordinarily occurs between the second and seventh day following implantation of the dry material, but complete absorption of large amounts of blood-soaked material may take six weeks or longer.

Oxidized cellulose is of value as an aid in surgery for the control of moderate bleeding under conditions where suturing or ligation is technically impractical or ineffective. Such situations include the control of capillary, venous or small arterial hemorrhage encountered in operations on the biliary tract, partial hepatectomy, resections or injuries of the pancreas, spleen or kidneys, bowel resections, amputations, resections of the breast, thyroid and prostate and in certain aspects of neurologic and otolaryngologic surgery. Oxidized gauze is employed as a sutured implant or temporary packing depending on the anatomic site or structures involved. Oxidized cotton is used primarily for neurologic surgery as unsutured packing, small portions of which may be left unremoved to control small areas of oozing from the dura or brain tissue. This material is likewise useful as temporary packing for control of secondary hemorrhage following adenoidectomy, tonsillectomy and other oral procedures and for control of alveolar bleeding following tooth extraction. Neither oxidized gauze nor cotton should be used for permanent packing or implantation in fractures; because it interferes with bony regeneration and may result in cyst formation.

The hemostatic action of oxidized cellulose is not enhanced by the addition of other hemostatic agents such as thrombin, which would be destroyed by the low *p*H of the material, and it has been shown that the hemostatic action of either alone is greater than the combination. The hemostatic effect is greater when the dry material is applied, so that moistening with water, or sodium chloride solution is not recommended. When properly used, oxidized cellulose may be closed in a clean wound without drainage, but this is hazardous whenever gross contamination is suspected or frank infection is present.

Neither oxidized gauze or cotton should be used as a surface dressing except for the immediate control of hemorrhage, as cellulosic acid inhibits epithelialization.

Dosage—The amount of oxidized gauze or cotton used varies with the circumstances of the particualr case. As a general rule, only the minimal amount required to control hemorrhage should be used. For the control of hemorrhage from the prostatic bed, this may vary from one to four 2 by 14 inch (5.18 by 35. 6cm.) gauze packing strips, depending on the extent and vascularity of the area to be packed and the technic employed. This size of oxidized gauze is particularly designed for implantation by means of mattress sutures. Gauze packing strips ½ inch by 2½ yards (1.27 by 228.6 cm are adapted for otolaryngologic or dental procedures; cotton pads 2 by 6 inches (5.08 by 15.24 cm.) are designed for neurologic, oral and/or dental surgical procedures.

In the event that it is desired to remove gauze or cotton from a hollow viscus or drainage site before dissolution is complete, removal can be facilitated by irrigation.

Tests and Standards.—

Oxidized cellulose in the form of gauze or cotton is slightly off-white in color, is acid to the taste and possesses a slight charred odor. It is soluble in dilute alkalie but insoluble in acids and water.

The solution obtained by vigorously shaking for one minute 200 mg. of oxidized cellulose in 10 cc. of 1 per cent aqueous sodium hydroxide solution, followed by the addition of 10 cc. of water, shows only a few fibers or foreign particles and only a slight haze. The presence of some swollen fibers may be tolerated if such fibers disappear when the solution has been standing for ten minutes. Addition of excess acid to the prepared solution causes a white, flocculent precipitate.

The moisture content of a 200 mg. sample of oxidized cellulose, when dried in vacuum over phosphorus pentoxide for twenty-four hours, does not exceed 15 per cent.

The residue on ignition of an accurately weighed specimen of oxidized cellulose does not exceed 0.15 per cent of the weight of the gauze or cotton.

Place 0.5 Gm. of oxidized cellulose, weighed to the nearest milligram, in a 125 cc. Erlenmeyer flask. Add 50 cc. of quarter-normal calcium acetate to the flask and swirl the contents until the sample is completely covered. Allow the mixture to stand for thirty minutes at room temperature, then titrate the solution with tenth-normal sodium hydroxide, using 5 drops of 5 per cent phenolphthalein T.S. as the indicator. Correct the titration by a blank run on 50 cc. of the calcium acetate solution. Each 1 cc. of tenth-normal sodium hydroxide is equivalent to 0.0045 Gm. of carboxyl group. The carboxyl content is not less than 16 per cent or more than 22 per cent, calculated on the dry basis.

Place a 1 Gm. sample of oxidized cellulose, weighed to the nearest milligram, in a 500 cc. Kjeldahl flask. Arrange a 125 cc. Erlenmeyer flask, containing 30 cc. of 4 per cent boric acid solution and 6 drops of mixed indicator (1 part of 0.1 per cent methyl red T.S. and 4 parts of 0.1 per cent bromcresol green T.S.); beneath the condenser of the distillation apparatus so that the tip of the condenser is well below the surface of the boric acid solution. Add to the Kjeldahl flask containing, the sample 1 Gm. or Devarda's alloy (50 per cent copper, 45 per cent aluminum and 5 per cent zinc), 100 cc. of ammonia-free distilled water, a small lump of paraffin wax and 100 cc. of 5 per cent sodium hydroxide solution. Connect the Kjeldahl flask to the condenser by a suitable trap bulb. Heat the mixture in the flask until 45 to 50 cc. of distillate has collected in the receiver. Rinse the condenser and titrate the boric acid solution with tenth-normal sulfuric acid to a pale pink endpoint. Correct the titration by a blank run on the reagents in identical fashion. The nitrogen content shall not be more than 0.5 per cent, calculated on the dry basis.

To 1 Gm. of Oxidized cellulose in a 300 cc. Florence flask add 120 cc. of one times normal sulfuric acid and a few glass beads. Connect the reaction flask to an apparatus arranged for distillation with a dropping funnel filled with distilled water entering the flask. Transfer 10 cc. of a sodium bisulfite solution (13.7 Gm. sodium bisulfite or 12.5 Gm. sodium metabisulfite per liter in water) into a receiver so that the condenser outlet is submerged in the bisulfite solution. The contents of the reaction flask are heated to boiling, and during distillation distilled water is added to the reaction flask from the dropping funnel at such a rate that the volume of the contents of the reaction flask is not appreciably altered. Carry on the distillation for one hour, collecting 250 to 300 cc. of distillate. Cool the distillate, if warm, and allow it to stand for fifteen minutes to insure complete reaction of the bisulfite and formaldehyde. Add 1 cc. of starch T.S. and destroy the excess bisulfite by addition of tenth-normal iodine solution until a blue color is obtained. Discharge with a drop or two of tenth-normal sodium thiosulfate. Add 5 cc. of saturated sodium bicarbonate solution and titrate the liberated bisulfite with tenth-normal iodine. As the endpoint is approached, signaled by the very slow consumption of iodine, 0.5 cc. portions of half normal sodium carbonate are added, which discharge the blue color. The endpoint is reached when 1 cc. of the sodium carbonate solution does not discharge the blue color over a period of half an hour. Too great an excess of sodium carbonate is to be avoided since at high *p*H the iodoform reaction may take place with an increased consumption of iodine. Each cc. of tenth-normal iodine solution is equivalent to 1.5 mg. of formaldehyde. The formaldehyde content should not exceed 4.5 per cent of the weight of oxidized cellulose calculated on the dry basis.

EDITORIAL ANNOUNCEMENT

The absence of the compositors employed by the American Medical Association from their work continues. This issue of THE JOURNAL has been prepared largely by the use of Vari-Typer machines. Because of the difficulties of reorganization of the headquarters office necessitated by this situation, the editorial material in this issue of THE JOURNAL has been greatly condensed.

LEPROSY

World War II caused disruption of research on leprosy, and took essential personnel but did not stop progress. The most outstanding advancement in leprosy was made in clinical treatment. In 3 cases reported in a review by Dr. James A. Doull[1] successful surgical removal was apparently made of the primary lesion. In 2 cases evidence of dissemination of the disease had not appeared eleven years postoperatively. In the third case, that of a patient operated on in 1916, evidence of leprosy had not appeared on reexamination in 1944, twenty-eight years after excision of the original lesion. Use of diphtheria toxoid was considered to have failed to show beneficial results in treatment. This was equally true of transfusions of pooled blood plasma. Calcium gluconate was reported to give beneficial results when administered intravenously in cases of painful neuritis.

Preliminary reports of treatment with streptomycin were inconclusive. Many toxic manifestations were encountered, the most serious being tinnitus, impaired hearing and exfoliative dermatitis, and other reactions found to be associated with streptomycin therapy in other diseases.

Two groups of workers reported unsuccessful use of penicillin treatment. Dosages reached 100,000 units daily for periods of more than two weeks. Technics used were intramuscular injection every three hours, intravenous drip eight to ten hours daily and daily intramuscular injections of the drug in peanut oil and beeswax. The authors of these papers concluded that penicillin seemed to be useful in patients with secondary infections caused by streptococci or staphylococci. The dosages of penicillin were relatively small compared with extremely high penicillin dosages which have been found necessary for successful treatment in many cases of subacute bacterial endocarditis failing to show improvement on lesser dosage.

One author reporting on chaulmoogra oil stated that disagreement regarding therapeutic value of chaulmoogra is due essentially to lack of uniformity in selection of cases. Only the lepromatous type should be considered. He believed that the use of derivatives of chaulmoogra oil had achieved persistent clinical and bacteriologic negativation of lepromatous cases.

Dr. Doull reemphasizes the necessity for controlled case studies with the newer drugs. There is apparently some danger that plans for such control tests may be sabotaged on the one hand by a demand for treatment by every patient and on the other by the insidious belief that the response of treated patients furnishes a sufficient guide. The deceptive course of leprosy and the present continued uncertain position of chaulmoogra oil in therapy after years of administration is certainly convincing evidence of the necessity for adequately controlling experiments with newer drugs.

Sulfone drugs which have been used in leprosy are "promin," "diasone," "promizole" and "sulphetrone." The active principle of each of these seems to be diaminodiphenyl sulfone, the basic chemical from which they are derived. These drugs vary greatly in solubility and toxicity. The first report made by Faget and associates[2] stated that "promin" seemed to possess some chemotherapeutic property in leprosy, as evidenced by the apparent inhibition of the progress of the disease. This observation was subsequently confirmed by the same and other observers, who found that the improvement in leprosy under "promin" therapy is not accompanied by characteristic cellular changes. Cellular changes which do occur are atrophic in character, with extremely slow and gradual lessening of numbers of organisms in the lesions to the point of final disappearance. These changes do not differ materially from changes occurring during spontaneous remission without treatment of any sort. The important observation is apparently that "promin" eliminates bacillary infection in the blood vessels and blood stream, thereby preventing spread to new areas. Atrophy of focal lesions was found in locations with generous blood supply. Final conclusions were that a more highly bactericidal agent than "promin" appears necessary for chemical destruction of bacilli within tissue cells.

---

[1] Doull, J. A; The Journal: A Review of the Scientific Papers, Internat. J. Leprosy 15: 444-465 (Oct.-Dec.) 1947.

[2] Faget, G. H., and others: The Promin Treatment of Leprosy: A Progress Report, Pub. Health Rep. 58: 1729-1741 (Nov. 26) 1943.

"Diasone" was reported on favorably in Trinidad, British West Indies, the National Leprosarium at Carville, La., and in Rosario, Argentina. Encouraging improvement occurred in patients treated, but bacilli did not completely disappear from lesions.

"Promizole" appeared to be well tolerated by patients with leprosy. Clinical improvement occasionally could be demonstrated more quickly with this drug than with "promin" or "diasone." There is disagreement with this on the basis that such a difference is not definitely established. This together with the distastefulness of the drug and its relative expense has led to its discontinuance in some clinics. "Sulphetrone" has been tried on only a few patients over a period of six months. Results are promising, and only mildly toxic symptoms have been observed.

Successful treatment of lepromatous ulcers was reported in 14 of 15 patients treated over periods varying from nineteen to seventy-five days with a 2 per cent alcoholic solution of tyrothricin. This solution is applied to ulcers in spray form. Crude streptomycin broth used locally has also been favorably reported.

Faget and Erickson[3] have stated that the sulfone drugs "promin," "diasone" and "promizole" produce objective clinical improvements in leprosy which are sustained and cannot be attributed to spontaneous remissions in the disease. These objective improvements, although slow in development, are progressive during the course of treatment. These authors[3] concluded that the sulfone drugs must be considered the optimal remedy for leprosy until faster acting remedies are discovered.

The long, unsettled and unsatisfying experience with chaulmoogra oil dictates that considerable caution be exercised in ascribing antileprotic qualities to any drug. However, recent developments with the sulfone derivatives indicates the probablity that a true chemotherapeutic agent may soon be discovered.

FAINTING AND FLYING

Romano and Engel[1] stated that encephalograms taken during actual loss of consciousness may be classified in three groups: the emotional type of fainting, the epileptic type and the syncopal or vasodepressor type. Rook similarly classified 500 cases of impairment of consciousness in pilots and air crew studied at the Central Medical Establishment, Royal Air Force. He considered the pathologic processes that led to the attack to result from three separate mechanisms: disturbances of the highest cortical levels; hypersensitivity of the nerve cells at the lower level leading either to explosive discharge or to pathologic inhibition, and alterations in the quantity or quality of the blood supply to the brain. The essence of loss of consciousness affirmed Rook, must be some change in the nerve cells themselves, whether brought about by mechanical, chemical or electrical agencies. Rarely in any case is only one of these pathologic processes at work. For example, emotion may be the trigger that unlooses an epileptic fit or causes an attack of syncope, as pointed out by Penfield and Erickson. The differentiation between an epileptic attack and cardiovascular syncope is not always easy. Epilepsy may be characterized by flaccidity rather than by convulsions, and convulsive movements are often seen in syncope. A reliable record of the patient is important. Psychiatric examination is helpful. Much controversial discussion ranges about the value of electroencephalograms. The exact value of encephalographic study has not been completely determined. A positive or negative electroencephalogram may be suggestive but no more. An electroencephalogram was done on 299 of the patients in Rook's series. In the neurogenic group nearly 50 per cent of the electroencephalograms pointed to an epileptic basis for the attack; in the other groups 15 per cent were positive. A change in the electroencephalogram when repeated occurred in 11 instances.

Of the 500 cases studied by Rook, 120 (24 per cent) were regarded as primarily neurogenic, 154 (31 per cent) as primarily due to some cardiovascular cause and 208 (42 per cent) as primarily emotional in origin. Seventeen cases could not be accurately classified. Pilots appear more likely to be affected than air crews. Fifty-three cases were definitely epileptic in origin, and 6 others were almost certainly epileptic. Hyperventilation of emotional origin in pilots and air crew was a frequent and a definite factor in the production of epilepsy. Fainting due to cardiovascular causes occurred because of cerebral anemia, cerebral congestion or some alteration in blood chemistry. Cerebral anemia was associated with heart disease, pain and hypotension; only rarely with hypertension. Cerebral anemia could be brought on by fatigue, excessive heat or cardiovascular inefficiency. Four instances concerned cerebral congestion and loss of consciousness associated with coughing.

The importance of emotion as a factor in the causation of loss of consciousness, particularly in wartime, is well known. Fear and anxiety and the various types of reaction to them are responsible for panic states and particularly for anxiety states. Inability to sustain the stress of flying and associated anxiety was present in 117 cases of this series. Simulation occurs in a few cases and is difficult to differentiate from hysteria.

ELECTROPHORESIS AND PROTEIN FRACTIONATION

The methods of protein fractionation based on physical differences between the various fractions are peculiarly suitable for the identification and isolation of active protein principles. Even mild chemical treatment, such as precipitation with alcohol, appears at times to denature the active protein principle. In electrophoresis proteins are fractionated according to their rate of movement in an electrical field; this is dependent on the charge on the protein molecule and on its size and shape. In this procedure serum proteins are divided into the principal fractions: albumin; *alpha, beta and gamma globulins,* and *fibrinogen.*

The fractions obtained by electrophoresis, however, should not be considered to be chemically homogeneous without additional evidence, such as chemical analysis, crystallization, ultracentrifugal analysis and, perhaps most important, constant solubility. Insulin, for instance, appears to respond the same to electrophoresis, whether the preparation is crude or purified. In the study of pepsin and chymotrypsinogen, solubility has proved to be a more sensitive criterion of purity than electrophoresis. The electrophoretic fractionation of serum is dependent on the buffer which is used; thus, the alpha-*1*-globulin in barbiturate buffer is included in the albumin fractions when phosphate buffer is employed.

Characteristic electrophoretic patterns of the blood serum proteins have been found to be diagnostic of only a few diseases, such as nephrosis and some types of myalomatosis. Nephrosis is characterized by a profound reduction in serum albumin and gamma globulin while the alpha and beta globulins are increased. In most other cases, however, the electrophoretic picture appears to be characteristic not of the specific disease but of the host's reaction to infection or injury. The common denominator of almost every pathologic state thus examined is a relative or absolute decrease in serum albumin. Severe bodily injury, such as that due to burns, freezing or fractures of bones, results in decreased albumin and increased alpha globulin concentration. Infection results in two distinctive changes in the globulin fraction; in the febrile state there is usually an increase of alpha globulin to several times the normal concentration, though an exception to this increase is seen in malaria vivax due to Plasmodium. A later change is an increased concentration of gamma globulin, the fraction in which antibodies are found. In many infections fibrinogen is increased at an early stage along with alpha globulin. In tuberculosis the pattern changes with the progress of the disease: initially the gamma globulin is elevated, then the alpha-2-globulin increases, and in far advanced cases all globulin fractions are augmented. Because of a decrease in albumin the total proteins remain essentially constant. The electrophoretic patterns of other pathologic states have also been reported, but, as with many chemical and physiologic measurements in disease, this information cannot in most cases be expected to yield a specific diagnosis of the disease. Additional information is needed for the more adequate interpretation of changes in plasma proteins.

Current Comment

ELECTROLYTES AND WATER IN SHOCK

"Shock is a syndrome resulting from the depression of many functions, but in which reduction of the effective circulating volume and blood pressure are of basic importance and in which impairment of the circulation steadily progresses until it eventuates in a state of irreversible circulatory failure."[1] Extended discussion on the nature of the initiating factors in shock has appeared during the past quarter of a century with varying emphasis on their relative importance; however, the ultimate result is diminution of fluid within the blood vessels and the accompanying deleterious hemodynamic effects. Circulatory collapse is the outstanding clinical feature of shock from trauma or burns; in both circumstances it has not been possible to account satisfactorily for the loss of circulatory fluid by the accumulation of water in the tissues or the loss from the surface. A recent report[2] describes experiments designed to trace this "lost" water by following the shift in electrolytes from tissues subject to mechanical injury and to burns. With mice as the subjects, traumatic shock was produced in one hind leg and the opposite leg served as a control. There was a decided loss in potassium and a gain in sodium and water in the injured tissue. As sodium is the characteristic cation of extracellular fluid and potassium holds a like position in cell sap, the conclusion was reached that injury causes a loss of potassium from the tissue cells and a concomitant replacement with sodium and water, thus explaining the local edema. The passage of sodium from the extracellular fluid into the cell lowers the osmotic pressure of the extracellular fluid in the injured tissues and brings about the uptake of water which was observed in the control leg. Similar results were secured when shock was produced by immersing the leg in water at 75 C. The foregoing observations have been interpreted to indicate that as a result of trauma there exists an obvious loss of water as edema fluid or "weeping" at the site of injury and also a hidden loss brought about by swelling of all the uninjured cells of the body. Both circumstances contribute to the reduction of fluid in the circulatory system, thus setting the stage for the development of the clinical signs of shock. A secondary factor is the toxicity of the potassium liberated into the circulation from the injured tissue cells. Measures that are designed to reestablish normal extracellular fluid volume and concentration of sodium while removing the excess potassium would seem to constitute a rational first approach to effective therapy.

Official Notes

MEETING OF THE BOARD OF TRUSTEES

A CONDENSED REPORT

Chicago, Feb. 19 and 20, 1948

The meeting of the Board of Trustees in Chicago on February 19 and 20 was fully attended, with the exception of Dr. John H. Fitzgibbon.

Fourth International Congresses on Tropical Medicine and Malaria

The Board voted to join the Fourth International Congresses on Tropical Medicine and Malaria as a sustaining member.

Grass Roots Conference

It was decided that the Grass Roots Conference shall be a part of the Annual Session in June and that it shall be held on Sunday afternoon as heretofore. Dr. A. M. Mitchell was selected as chairman of the conference.

Appointment of Representatives

Representatives were appointed to the Committee on Maternal and Child Health and Crippled Children's Services, to the American Academy of Political and Social Science, to the annual meeting of the British Medical Association, to the Midwest Physical Education Association, to the National Conference on Higher Education, to the ninth International Congress on Industrial Health to be held in London September 12-17 and to the Conference on Human Rights and Freedom of Information to be held in Washington, D. C., on March 4.

Dr. Fishbein was authorized to serve as chairman of the council of the International Medical Press, which proposes to hold a conference of medical editors of the world within the next few years.

Drs. E. L. Henderson and R. L. Senseñich were appointed as delegates to the meeting of the World Medical Association and Drs. E. E. Irons and Morris Fishbein as alternates.

Consultant for Council on National Emergency Medical Service

The appointment of Dr. Hugh Morgan as a consultant to the Council on National Emergency Medical Service on matters pertaining to the Army was approved.

Committee Appointments

The following committees were appointed: Committee on Hospital Competition with Private Practice; Committee to Work with the American National Red Cross on its blood bank program, and a Committee to work out a plan for the selection of the recipient of the General Practitioner's medal.

International Congress of Leprosy

Mr. Ralph Creer, secretary of the Committee on Medical Motion Pictures of the A.M.A., was authorized to accept an invitation from the Leonard Wood Memorial Institute (the American Leprosy Foundation) to attend the International Congress of Leprosy, which is to be held in Havana, Cuba, April 3-11.

Appointment of Consultants for Council on Industrial Health

Authorization was given to the Council on Industrial health for the appointment of a group of consultants having special attainments in the field of workmen's compensation to assist in the proper evaluation of medical and administrative policy and relations.

Exhibit on Medical Aspects of Atomic Energy

Approval was given for an exhibit by the Council on Physical Medicine at the Chicago Session on the medical aspects of atomic energy.

Session on Physical Medicine of Section on Miscellaneous Topics

Authorization was given for a Session on Physical Medicine in the Section on Miscellaneous Topics at the June Session of the Association

Conference on Nomenclature

Authorization was given for the calling of a conference on nomenclature on Wednesday afternoon, June 23, in the headquarters of the Association.

Survey of Medical Education

The following proposals of the Council on Medical Education and Hospitals were approved:

1. That the survey of medical education should be initiated at the earliest possible date.
2. That a committee consisting of Drs. Arthur C. Bachmeyer, Joseph C. Hinsey, Victor Johnson, and H. G. Weiskotten, and the secretaries of the Council on Medical Education and Hospitals and the Association of American Medical Colleges ex officio, supervise the conduct of the survey and prepare and publish a report.
3. That the employment of a full time director and such other personnel as may be needed to conduct the survey be authorized.
4. That the headquarters of the survey be maintained in the office of the Council on Medical Education and Hospitals.
5. That this survey be designated a Survey of Medical Education, sponsored by the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical College, and be conducted by the committee whose membership is listed in paragraph 2.

The Board suggested that the name of an outstanding educator be added to the names of the committee members mentioned in paragraph 2, and the suggestion was adopted by the joint-committee.

Appointments to Editorial Boards, Councils and Committees

Appointments were made to various editorial boards, councils and committees to fill vacancies caused by the expiration of terms of service.

Dr. Stanley J. Seeger Named Emeritus Chairman of Council on Industrial Health

The Board voted that Dr. Stanley J. Seeger, who recently resigned from the Council on Industrial Health, be named emeritus chairman of that Council.

Fund-Raising Campaign of American Cancer Society

The Board authorized the publication of an editorial in support of the campaign of the American Cancer Society for funds.

Successor to Dr. Lloyd Noland on Judicial Council

The Board noted with regret the resignation of Dr. Lloyd Noland from the Judicial Council and approved the appointment by the President of Dr. Homer Pearson to fill the vacancy on the council until the next meeting of the House of Delegates.

Nurse Anesthetists

The attention of the Board was called to articles being published in the lay press regarding nurse anesthetists, and it was voted to condemn publicity that is not based on a scientific understanding and that does not accurately reflect the prevailing situation.

Handbook of American Medical Association

The Board voted to publish an announcement in THE JOURNAL that copies of the Handbook of the American Medical Association are available in the headquarters office.

American Academy of General Practice

A conference was held with officers of the American Academy of General Practice, and the Board appointed a liaison committee to that organization, consisting of Dr. Harvey B. Stone from the Council on Medical Education and Hospitals, Dr. E. J. McCormick from the Council on Medical Service and Dr. Wingate M. Johnson from the Board of Trustees.

Proposed Amendment to Internal Revenue Code

The Board authorized its representatives to a meeting of the New York Bar Association to record the vote of the Board in support in principle of the proposal that the Internal Revenue Code be amended to permit physicians doing business as a partnership to deduct the cost of a pension program for themselves and to accord physicians and others doing business as proprietors the same privilege, with the proviso that there should be a reasonable maximum.

Voluntary Support of Medical Education

The need and desirability of developing and organizing a continuing program on a national scale for the promotion of voluntary support of medical education was recognized and the Board authorized that a campaign be conducted.

Funds for Medical Education

In considering bills S. 145 and H. R. 3925, the Board expressed disapproval of the use of federal funds for medical education in any manner by which the government would enter into control.

Registration and Approval of Hospitals for Internship and Residencies

At a meeting on Saturday of a special committee appointed by the Board of Trustees and representatives of the American College of Surgeons, the Council on Medical Education and Hospitals, the American Board of Surgery, the American Board of Orthopedic Surgery and the Advisory Board for Medical Specialties, it was decided to appoint a committee of seven; two members to represent the American Medical Association; two, the American College of Surgeons; two, the specialty boards in surgery, and the secretary of the Advisory Board for Medical Specialties to study the whole matter of the registration of hospitals and their certification for internships and residencies and to work out a mechanism that will avoid duplication. The conference group selected Drs. W. M. Firor of Baltimore and Guy A. Caldwell of New Orleans to represent the specialty boards in surgery; the special committee of the Board selected Drs. Harvey B. Stone and Donald G. Anderson to represent the American Medical Association, and Drs. F. A. Coller of Ann Arbor, Mich., and Dallas Phemister of Chicago have been appointed by the board of regents of the American College of Surgeons to represent that organization. The secretary of the Advisory Board for Medical Specialties is Dr. B. R. Kirklin.

Correction of Inaccuracies in Pronouncement of Dr. Parran Re Shortage of Physicians

The Board voted to request correction of the inaccuracies in the pronouncement of Dr. Thomas Parran, Surgeon General of the United States Public Health Service, with respect to the critical shortage of physicians in the United States which he anticipates will develop by 1960.

Medical Motion Picture Film for British Medical Association

The Board voted to send, with the compliments of the Association, a copy of its film "Medical Motion Picture: Its Development and Present Application" to the Library of the British Medical Association.

Dr. Fishbein to Cooperate in Preparation of Series of Medical Motion Pictures

The Board authorized Dr. Fishbein to continue negotiations with film producers with a view to extending medical education to the public through the use of scientific medical pictures.

Miscellaneous

Many other subjects were considered. Some of them will no doubt come up again for action.

WASHINGTON LETTER

(From a Special Correspondent)

Feb. 18, 1948

Shortage of Physicians in Armed Forces on Increase

Rear Admiral Joel T. Boone, executive secretary, Armed Services Committee on Medical and Hospital Services, following a tour of Army, Navy and Air Force hospitals reported that the shortage of physicians in the armed services is increasing and may endanger the health of American fighting men. The committee is studying possible administrative changes in the service medical departments as a result of unification. Admiral Boone explained that about half of the military physicians now on duty will leave service by July 1, 1949, when the Navy V-12 and the Army specialized training programs end. Under these programs young men were taken into the services and trained as physicians. The admiral estimated that the Navy's staff of physicians would drop frmm 2.900 to 1,482 while the Army would lose about 3.000.

Veterans' Budget Seeks More Medical Personnel

The proposed 1949 budget of the Veterans Administration is reported to provide for a slight increase in medical personnel but a decrease in administrative workers. Veterans Administrator Gray is reported to have refused the request of a House Veterans Committee to delay the current dismissal of 8,500 employees of the agency. The committee had asked for delay in their release until the effect of such dismissal on service to veterans could be ascertained. The agency in a statement explained that the cuts in staff were ordered because present funds "are not sufficient to maintain services and employment at the present level."

Committee Approves Funds for Research Center

The House Appropriations Committee approved immediate provision of $5,000,000 and authorization to spend $40,000,000 to build an eight hundred bed hospital and research center at Bethesda, Md., to house research on mental disorders, heart disease and cancer. The committee reported out the Labor-Federal Security supply bill for 1949 and added $8,000,000 to the original request for funds for the center. An escalator clause was inserted to assure that work starts promptly and that the center is completed as soon as possible. The Federal Security Agency is permitted to contract in excess of $40,000,000 if rising costs of building make this necessary.

GOVERNMENT SERVICES

ARMY

NEW APPROACH TO CONTROL OF VENEREAL DISEASE

Following studies made in 1946, the Army developed a new approach to the control of venereal disease. A phenomenal decrease in the number of cases in American soldiers occurred during 1947. The decrease for the Army as a whole amounted to 40 per cent, and among the soldiers stationed in the United States it amounted to more than 50 per cent.

In considering methods for the control of venereal disease the general staff established the Army Venereal Disease Control Council. Local councils were established at all military installations. There emerged a program, now employed, based on moral, spiritual, psychologic and objective factors. This broadened approach has supplanted previous concepts. Today stress on the moral reasons for good conduct is imparted to the troops through group and individual instruction. Planned entertainment helps to maintain the wholesome interest of the soldier and keeps him off the street when he is off duty. A further aid was the recall of all training films used during the war for venereal disease control and the production of new films reflecting the present program. The first in the new series of motion pictures is entitled "The Miracle of Living"; it dramatizes the rewards of good conduct as well as the effects of venereal diseases on the person's future.

ARMY NURSE CORPS RESERVE

The Surgeon General has summoned fifty Army Nurse Corps leaders to Washington for a two day conference to map out a program to enroll 29,000 Army Nurse Corps officers during 1948, about 25,000 of whom are to accept commissions on an inactive status, continuing in their civilian posts except in time of national emergency. Attending the conference are chief nurses of the six Army areas in the United States and of Army general hospitals and the directors of nursing services in the Far East Command, in Europe and the Antilles.

Under the provisions of an act of Congress of 1947, the Army Nurse Corps became a permanent branch of the military establishment. The law provided for the formation of a reserve corps through which all future assignments of nurses to extended active duty will be made. About two thousand such assignments will be available during 1948.

MEDICAL MEETING IN KOREA

About seventy-five officers attended the medical meeting February 18 at the 382d Station Hospital in Korea The forenoon was given over to ward rounds and departmental conferences. In the afternoon Major Robert M. Hardaway, chief, surgical service, 34th General Hospital, read a paper on regional ileitis; treatment was discussed by Lieut. Wilbur A. Thomas of the 34th General Hospital. Lieut. Col. Warner F. Bowers, surgical consultant (GHQ, FEC) discussed abdominal trauma and the cases observed on the surgical ward rounds. Lieut. Ross A. Miller, chief, surgical service, 382d Station Hospital, read a paper on acute intestinal obstruction, which was discussed by Lieut. Cecil A. White of the 382d Station Hospital and Lieutenant Col. Bowers. Capt. Myrtle N. Nereson, chief, principal nurse, 382d Station Hospital, discussed "The Nursing Care of Colostomies" The scientific session was under the direction of Lieut. Col. Watson E. Neiman, commanding officer, 382d Station Hospital, and the business meeting was presided over by Col. Charles P. Ward, surgeon, 24th Corps. A buffet dinner and social hour were held at the Officer's Club in the evening.

NAVY

NEW REGULAR OFFICERS

The *following five* lieutenants (jg), all graduates of the Navy's V-12 program, have been transferred to the Regular Navy Medical Corps: Richard B. Connor, Columbia, S.C.; Kevin A. Doyle, Glenbrook, Conn.; Avery L. Cotton, Houston, Texas; Charles L. Lear, Montebello, Calif.; and Fred A. Valusek, Newburgh, N.Y.

The following physicians from civil life have recently been commissioned lieutenants in the Regular Navy Medical Corps: George E. Gardner, Philadelphia, and James M. Tuholski, Memphis, Tenn.

RESERVE OFFICERS NOMINATED FOR DUTY

The following lieutenants (jg) of the naval medical reserve, *having completed* the basic refresher course at the Naval Medical School at Bethesda, Md., have been nominated for duty; James E. Hull, Columbia City, Ind.; Dwight H. Smith, Cherry Point, N.C.; DeWitt T. Brock, Camp Lejeune, N.C.; James R. Clarkin, Bronx, N.Y.; John R. Lindsay, *Wilmington*, Del.; Charles E. Boonstra, Lafayette, Ind.; Richard K. Williams, Richmond, Va.; Archie G. Britt, La-Crosse, Wis.; John E. LeDonne, Revere, Mass.; Howard H. Lyons, Linwood, Mass.; Donald H. McCowan, West Chester, Penn., and Grover C. Nabors, Goldville, S.C.

GRADUATE TRAINING

The following medical officers have been approved for graduate training: Comdr. Edward G. Hurlburt, residency in dermatology and syphilology at a Navy Hospital.

Comdr. Joseph A. Forte, course in internal medicine at University of Pennsylvania Graduate School of Medicine, beginning October 1948.

Lieut. Comdr. Ralph D. Ross, additional year's training in internal medicine at the Naval Hospital, San Diego, Calif.

Lieut. (jg) Robert W. Williams Jr., residency in in internal medicine at a Naval hospital.

Lieut. Dale B. Watkins, additional year's training in internal medicine at the Naval Hospital, San San Diego, Calif.

Lieut. (jg) Orville M. Graves Jr., residency in ophthalmology at the Naval Hospital, San Diego, Calif., transfer to U. S. Navy.

Lieut. (jg) John R. Huston, residency in pathology at a Naval Hospital.

Comdr. Lewis E. Hedgecock, course in preventive medicine and venereal disease control at Johns Hopkins University School of Hygiene and Public Health, Baltimore.

Comdr. William F. Lyons, course in preventive medicine at Harvard University, Boston.

Comdr. Theodore E. Hoffman, residency in surgery at the Naval Hospital, Great Lakes, Ill.

Comdr. Richard Lawrence Jr., residency in internal medicine, U.S. Naval Hospital, San Diego, Calif.

Lieut. (jg) Preston R. Bandy, residency in anesthesiology, Naval Hospital, Bethesda, Md.

Comdr. Ronald N. Shelley, course in thoracic surgery and endoscopy at George Washington University School of Medicine, Washington, D.C.

Lieut. (jg) James I. Thorn, training in aviation medicine, School of Aviation Medicine and Research Naval Air Station, Pensacola, Fla.

Capt. Julian Love, Comdr. Bishop L. Malpass, and Comdr. Ross W. Weisiger have completed a course of instruction in internal medicine at Cornell University Medical College, New York.

MISCELLANEOUS

ATOMIC COMMISSION TO SUPPORT CANCER RESEARCH

The Atomic Energy Commission is expanding its assistance to the nationwide work on cancer research by a program which involves radioactive materials, new facilities and financial aid. The program was designed to explore the possible benefits of atomic energy to those with cancer, to assist existing projects and to avoid duplication of work carried on by other governmental agencies, the American Cancer Society and privately endowed foundations and medical research centers. The main points of the commission's assistance are: (1) provision of radioisotopes for cancer research and treatment by qualified United States medical and research workers; (2) support of selected cancer research projects carried on by hospitals and universities; (3) establishment of research facilities, including limited hospital space at four laboratories of the commission, and (4) support of cancer research carried on by the Committee on Atomic Casualties of the National Research Council.

Effective April 1, 1948 all charges except those for handling and transportation will be removed from radioactive iodine (I 131) phosphorus (P 32) and sodium Na(24) to be used in the study and treatment of cancer. Other available useful radioisotopes will be added to the list, as it is determined that they can be supplied on the new basis. The commission warns that radioisotopes have not been found generally useful in cancer treatment as developed at the present time.

These radioisotopes under the new procedure will be obtained as heretofore from the Isotopes Branch, Atomic Energy Commission, Oak Ridge, Tenn.

I 131 has a relatively short half life. Half of its radioactivity is lost after eight days, half of the remainder by the end of the next eight days and so forth. The physician or investigator using the material must make allowance for loss of radioactivity as a result of time lost in shipment. If shipment requires five days, for example, a physician must order about 10 millicuries of I^{131} for every 6 millicuries of material he wishes to administer. The purchase price of I^{131} at Oak Ridge, Tenn., has been $1.70 per millicurie, the unit in which radioactivity is measured. Individual patients may receive a single application of only a few millicuries or a course of treatment extending over a period of weeks, so that the cost of material, apart from handling and shipping, may range from $20 to $200 or more. The price of Na 24 has been $12 per irradiated unit, which contains approximately 20 millicuries. This material has a relatively short half life, and, if an investigation is to extend for a considerable period of time, new lots of material must be procured at frequent intervals. Often an investigator will place an order for one or two units per week, extending over a period of six months or more, so that the saving in cost of material may amount to several hundred dollars.

In announcing increased support for selected cancer research projects related to atomic energy and carried on by independent institutions in various parts of the nation, the commission pointed out that projects which it supports are already under way at the Memorial Hospital for Treatment of Cancer and Allied Diseases, New York; Harvard University; the University of Rochester, and the University of California. At other institutions projects are being selected for support from the special fund for research on cancer now set aside by the commission.

Cancer research facilities will be established at Oak Ridge Hospital, Oak Ridge, Tenn ; Brookhaven National Laboratory, Long Island, N. Y.; Argonne National Laboratory, Chicago, and Los Alamos Laboratory, Los Alamos, N. Mex. Medical schools, clinics, hospitals and other research institutions in each region will be able to make use of the unique equipment in these installations.

The commission emphasized that its part is to provide the facilities to investigators or patients: the research will be carried on by the investigators, not by the commission; also, the hospital beds and research facilities will not be available for the treatment of cancer patients in general. With the limited number of beds, it is necessary that they be used for special studies which may benefit many who suffer with cancer through adding to basic knowledge, rather than solely for treatment of the few who can be accommodated.

FOREIGN SCHOLARSHIPS AVAILABLE SOON

The Fulbright Act authorizes executive agreements with foreign governments under which they may pay in part for sales of American surplus property overseas with scholarships and other educational enterprises in their own countries for American students. The State Department announces that in addition to agreements with China and Burma draft agreements are under consideration by the Philippines, Italy, New Zealand, Greece, Egypt and Belgium. Twenty-two nations are now eligible and are expected to participate in the plan, with an indication that more than $140,000,000 will be devoted to the program within the next twenty years.

Under agreements already completed China and Burma have placed at the disposal of the United States sums which will be used for financing studies, research, instruction and other educational activities for American students in schools in Burma and China. These sums include also the cost of transportation to and from the United States, tuition, maintenance and incidental expenses; they will permit Burmese and Chinese students to study in United States schools located outside this country as well as paying the cost of transportation of foreign students to and from the United States. Plans for making grants available to American scholars have not been completed, but public announcement will be made of the date when application can be received, which is expected to be early in 1948. Additional information can be obtained by writing the Division of International Exchange of Persons, Department of State, Washington 25, D. C.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARKANSAS

State Medical Meeting.—The Arkansas Medical Society will hold its annual meeting in Little Rock April 15-17 under the presidency of Dr. Lorenzo T. Evans, Batesville. Out of state speakers include:

Irvin E. Hendryson, Denver, Early Diagnosis of Poliomyelitis. Harry E. Bacon, Philadelphia, Cancer of Rectum, and Pelvic Colon.

Paul A. Davis, Akron, Ohio, General Practice of Medicine as related to the American Academy of General Practice. Hedwig S. Kuhn, Hammond, Ind., Industrial Ophthalmology. Ralph L. Ferguson, Vermillion, S.D., The Lymph Node as an Aid in Diagnosis. Carl A. Nau, Galveston, Texas subject to be announced. Richard Cattell, Boston, subject to be announced.

The Past-President's Breakfast will be held at the Hotel Marion April 17 at 7:30 a.m.

CALIFORNIA

Chronic Disease Survey.—At the direction of the 1947 state legislature, the state department of public health has formulated a plan for an extensive investigation of the "problems involved in the reduction of deaths and disability from cancer and other chronic diseases." The outline of the plan was approved by the state board of public health in November, and an advisory committee which was appointed at that time has held its initial meeting. Recommendations and estimated program costs will be placed before the legislature in 1949.

Open Nursery at Stanford Hospital.—A $20,000, fifty-eight crib nursery designed to prevent dangers of diarrhea and respiratory and cutaneous infections, was opened for inspection February 19 at Stanford University Hospital, San Francisco. Each crib is self contained, having its own equipment to prevent cross infection. Funds were provided by the late Mrs. Richard H. Shainwald and her brother, Walter D. Heller, San Francisco, in memory of their parents, Dr. and Mrs. Moses Heller.

FLORIDA

Annual Meeting of Board of Health.--The state board of health, at its annual meeting on February 10, recommended the expansion of four definite activities: abatement of stream pollution with special reference to Florida's beaches and streams; expansion of the Food Handlers' School; intensification of the school health program, and encouragement of counties to provide better quarters for their health units. The board reelected Dr. Herbert L. Bryans, Pensacola, as president. Dr. Wilson T. Sowder, state health officer, is executive secretary.

ILLINOIS

New Wing at County Hospital.--The Memorial Hospital of Du Page County, Elmhurst, recently opened a new $750,000 wing which adds one hundred beds to the one hundred and twenty-five beds in service, provides new surgical suites, a pediatric unit, auditorium and medical record library and will permit enlargement of the x-ray department, emergency section and delivery rooms. The Du Page County Medical Society, which henceforth will hold its meetings at the hospital, heard Dr. Willis J. Potts, Chicago, speak on "Recent Advances in Children's Surgery" at the opening of the new auditorium on February 18.

Chicago

Personal.--In January Dr. Leon Unger lectured on bronchial asthma before the Sociedad Mexicana de Alergistas in San Luis Potosi, Mexico, and later before the staff of the Children's Hospital, Mexico, D.F.

The Bacon Lectures.--Dr. Nicholson J. Eastman, professor of obstetrics at Johns Hopkins University School of Medicine, Baltimore, will deliver the annual Charles Sumner Bacon lecture at 1 p.m. April 14 at the University of Illinois College of Medicine on "Pelvic Mensuration; a Study in the Perpetuation of Error." The Bacon series was inaugurated in 1928 in honor of the late professor emeritus of obstetrics and gynecology. At that time members of the faculty and friends of Dr. Bacon contributed $5,000 to found the lectureship.

KANSAS

Dr. Murphy Appointed Dean.—Dr. Franklin D. Murphy, Kansas City, has been appointed dean of the University of Kansas School of Medicine effective July 1 to succeed Dr. Harry R. Wahl, dean since 1924. Besides serving as dean, Dr. Murphy will be an associate professor of internal medicine. He is the son of the late Dr. Franklin E. Murphy, a founder of the medical school and member of the faculty. Dr. Murphy obtained his medical degree at the University of Pennsylvania School of Medicine, Philadelphia, 1941; from 1944 to 1946 he was a captain in the army medical corps and worked with a research unit at Memphis, Tenn. Dean Wahl, who asked to be relieved of his duties as dean a year ago, will continue to teach at the medical school as head of the department of pathology.

LOUISIANA

Public Relations Program.—The Council on Medical Service and Public Relations of the Louisiana state Medical Society has developed a public relations program which provides for radio programs on health. A Speakers Bureau is to be established and lay persons and members of the profession will appear before all interested groups to talk on health, economics of medicine, voluntary health insurance and other subjects. An educational health column is to be released weekly for newspapers throughout Louisiana. A News Bureau will be established to disseminate information to the public relative to scientific advancements by members of the medical profession and to advise the public what the medical profession is doing in their behalf. The Louisiana Physicians Service, offering surgical and obstetric care, is sponsored by the Louisiana State Medical Society. It is proposed that the society assist in the establishment of health councils in every parish throughout the state. Other phases of the program include a closer relationship with other health agencies, societies and civic clubs and a campaign to enhance patient-physician relations. In general, the program will provide a medium to maintain adequate medical care at a cost which the patients can afford and at the same time to keep medicine a private enterprise.

MARYLAND

McCollum-Pratt Fund.—Johns Hopkins University, Baltimore, has received a $500,000 endowment, the McCollum-Pratt Fund, to be used for study of the function of copper, boron, cobalt, manganese and other minerals in living organisms. The principal and interest will be expended over a ten year period. The fund was named in honor of Elmer V. McCollum, LL.D., an authority on nutrition, and John L. Pratt, Fredericksburg, Va., university trustee and donor.

MICHIGAN

Ophthalmologic Clinics.—Dr. Albert D. Ruedemann, professor of ophthalmology, Wayne University College of Medicine, Detroit, will give clinics on beta irradiation in ophthalmology at the City of Detroit Receiving Hospital every other Wednesday from 10 a.m. to noon until June, beginning March 10. All ethical specialists are invited to attend.

MINNESOTA

Society of Anesthesiologists.—At a meeting in Minneapolis Nov. 15, 1947, a group of members of the American Society of Anesthesiologists formed the Minnesota Society of Anesthesiologists as an affiliate of the national organization. Dr. Ralph T. Knight, Minneapolis, was elected president and Dr. Frank Cole, Duluth, secretary-treasurer.

The Judd Lecture in Surgery.—The fifteenth E. Starr Judd Lecture will be given by Dr. Alfred W. Adson, professor of neuro-surgery at the Mayo Foundation, Rochester, April 29 at 8:15 p. m. in the Auditorium of the Museum of Natural History. Dr. Adson's subject is "The Evolution of Neurosurgery." The late E. Starr Judd, an alumnus of the University of Minnesota Medical School, established this annual lectureship in surgery a few years before his death.

Cancer Detection Center Opens.—A cancer detection center operating on a research basis opened in February at the University of Minnesota Hospital, Minneapolis. The effectiveness of examining apparently well persons in order to find early cancer will be determined. Persons who need treatment will be referred to their physicians. The center is financed by the Minnesota Division of the American Cancer Society, the U. S. Public Health Service and the University of Minnesota. Dr. David State of the hospital staff will serve as acting director. The center is to be open Tuesday and Thursday afternoons from 3 to 5 o'clock. Examinations will be by appointment only

Dr. Colvin Honored.—The surgical staff of the Ancker Hospital, St. Pall, honored Dr. Alexander R. Colvin at a dinner in the Minnesota Club January 19. Dr. Colvin has practiced in St. Paul since 1903 except for his service in the army medical corps during World War I. He has for the past thirty years been head of the surgical service of the hospital.

X-Ray Surveys at Colleges and State Institutions.—The Minnesota Department of Health launched its x-ray survey program in January. The goal is an annual roentgenologic examination of the chest of every Minnesota college student and all persons in state institutions. Colleges are assisting in financing the program. The state program combined with a community mass x-ray survey are expected by 1950 to bring to every person in the state an opportunity for roentgenologic examination.

MISSISSIPPI

Scholarship Loan Applications. -- The state medical education board has announced that all students interested in applying for medical education scholarship loans to become effective in autumn of 1948 should contact the Jackson office of the board, Room 37, North Street Building at once for information and application forms. Applications received during the spring months will be considered by the board on and after June 1. Over a hundred students have already requested applications for medical education loans to become effective in September.

NEW MEXICO

Clinical Society Lectures.—The New Mexico Clinical Society has arranged a schedule of lectures for the next few months to be held in the Museum of Anthropology, Santa Fe, with the following speakers:

April 16, Chester M. Jones, gastroenterologist, Harvard Medical School, Boston.

April 30, Francis Rackemann, allergist, Harvard.

May 3, Hamilton Montgomery, dermatologist, Mayo Clinic, Rochester, Minn.

May 14, Walter C. Alvarez, gastroenterologist, Mayo Clinic

June--Peter Heinbecker, surgeon, Washington University School of Medicine, St Louis.

July--Louis S Goodman, pharmacologist, University of Utah, Salt Lake City.

August--Oscar O. T Clagett, chest surgeon, Mayo Clinic, Rochester Minn. C. Allen Good, radiologist, Mayo Clinic, Rochester, Minn.

OHIO

Memorial Library.—The library at Peoples Hospital, Akron, consisting of about seven hundred selected volumes, including many of the current periodicals, has been named in honor of Dr. Jay D. Smith. He was interested in medical education and gave freely of his time and thought to Peoples Hospital while a member of the surgical staff from 1914 until his death, Nov. 17, 1947.

Appointed Head of Department of Urology.—Dr. Charles C. Higgins, Cleveland, has been named head of the department of urology at the Cleveland Clinic to succeed Dr. William E. Lower, one of the four founders of the Cleveland Clinic, who is retiring from active practice. Dr. Higgins graduated in medicine from Washington University School of Medicine, St. Louis, in 1923. He is president-elect of the American Urological Association, president of the Clinical Society of Genito-Urinary Surgeons and a member of the American Board of Urology.

PENNSYLVANIA

State Society to Publish History.—The history of the Medical Society of the State of Pennsylvania is being prepared in book form for publication in connection with the centennial celebration of the organization in October. Dr. Howard K. Petry, Harrisburg, former president of the society, is in charge of research, writing and production of the history. Authentic stories of unusual interest relating to physicians of bygone years will be welcomed by Dr. Petry for consideration. The headquarters of the society is at 230 State Street, Harrisburg.

Philadelphia

Faculty Appointments.—Hahnemann Medical College has announced the appointment of the following: Dr. John E. Gregory, Philadelphia, professor of pathology and head of the division of pathology; Amedeo Bondi, Jr., Ph.D., professor of bacteriology and head of the department, and Dr. Emerson A. Read, Quincy, Mass., assistant professor of physiology. Four newly appointed full time instructors in the clinical departments are Dr. Alexander W. Ulin, Cincinnati department of surgery; Drs. Otto H. Janton, Detroit, and Albert M. Lupton, Lewes, Del., department of medicine, and Dr. Joseph N. Seitchik, Philadelphia, department of obstetrics

County Postgradute Institute.—The twelfth Annual Postgraduate Institute of the Philadelphia County Medical Society will be held at the Bellevue Stratford Hotel, April 20-23. Topics to be discussed include: problems in obstetrics and gynecology, newer drugs and procedures, surgery of the ambulatory patient, fractures, the painful breast, neuropsychiatric disorders, problems of the aged, the acute abdomen, gastrointestinal disorders and otolaryngolical problems. At two evening sessions cancer and pediatrics will be discussed. For information address Dr. Gilson Colby Engel, Director, 301 South Twenty-first Street, Philadelphia 3.

TEXAS

Society Election.—The Texas Radiological Society on January 17 elected Dr. Leslie M. Garrett, Corpus Christi, president; Dr. John J. Faust, Tyler, president-elect; Dr. Roscoe P. O'Bannon, Fort Worth, secretary-treasurer. The next annual meeting will be held in Fort Worth January 7-8, 1949.

Rehabilitation Clinic Dedicated.—At a conference on physical medicine at the University of Texas Medical Branch, Galveston, a Rehabilitation Clinic in connection with the John Sealy Hospital was dedicated. Funds for the clinic were provided by the Monsanto Chemical Company, St. Louis, in appreciation of the services of the John Sealy Hospital in connection with the Texas City disaster last spring. Dr. Frank H. Krusen, professor of physical medicine, Mayo Foundation, Rochester, Minn., gave the dedication address.

WASHINGTON

Narcotic Violation.—Dr. Alphonse de Pierre-Hall, 302 South Thirteenth Street, Tacoma, pleaded guilty in the United States District Court in Tacoma to violation of the federal narcotic law and on January 2 was fined $1,500 and placed on probation for a period of six months.

Course in Applied Science.—The University of Washington School of Medicine, Seattle, has begun a course in the applications of basic sciences to disease. The course is arranged to bring together the physiologist, anatomist, biochemist, pharmacologist, pathologist and microbiologist with the clinicians. Classes, designed primarily for members of the resident staffs of hospitals who wish to qualify eventually for admission to specialty board examination, are being conducted each Thursday evening from 7 to 9 o'clock at Harborview Hospital Annex.

WEST VIRGINIA

Community Observes Doctor's Anniversary.—Dr. Edward L. McElfresh, Point Pleasant, completed fifty-five years of medical practice in Mason County on March 5, amidst a countywide observance of his anniversary. A program was arranged by the citizens of Point Pleasant and Mason County for the afternoon of March 7, and was attended by Dr. McElfresh's confreres from Mason and adjoining counties. In his honor a biographic sketch was read in all the schools of Mason County on March 5, pointing out the rigors of his pioneer practice and his modesty and devotion to duty throughout his fifty-five years of practice.

HAWAII

Annual Report of Board of Health.—Deaths from acute communicable diseases in the Territory of Hawaii reached an all time low in the fiscal year ending June 30, 1947, in spite of a rapidly expanding population. The tuberculosis death rate, after continuing at about 55 per hundred thousand population for several years, dropped to 49. However, the incidence of some communicable diseases showed an increase over the previous year: whooping cough from 9 to 616 cases; mumps from 277 to 597; chickenpox from 789 to 2329; typhus from 70 to 82 and poliomyelitis from 12 to 36. The leading cause of death is heart disease and the second is cancer. The population of the territory as of June 30, 1947 was estimated at 525,477, an increase of 1.2 per cent over the previous year. The crude mortality rate was six deaths per thousand population, the same as for 1946. The infant mortality rate for the territory was 31.2 per thousand live births, while it was 36.1 for the U. S. registration area in 1946. The maternal death rate for the territory dropped from 1.5 per thousand live births to 1.2 in 1947, the lowest ever recorded in Hawaii.

Child health conferences were held at regular intervals in one hundred and eighteen different locations throughout the territory and were participated in by fifty-one physicians, 5,608 infants, and 6,137 preschool children. Maternal health conferences were held at forty different centers by twenty-eight different physicians and were attended by 1,352 women.

The Bureau of Crippled Children had 2,305 crippled children under 21 years of age on the register, of whom 1,249 received some type of service from the bureau. During the year 382 new admissions were made to the register and 151 were discharged as cured, overaged or diseased. Fourteen traveling clinics which were held by the psychiatrist for the Bureau of Mental Hygiene served 359 patients and rendered 199 consultations concerning patients.

Human plague for the second successive year was not reported in the territory; however, 5 plague infections, 1 rodent, 1 mass flea inoculation, and 3 mass tissue inoculations were reported in the Hamakua district, the lowest number of plague infections reported in this area since 1932. One rodent plague infection was found on the island of Maui.

The Territorial Board of Health was designated by the governor as the agency to carry out the purposes of the new federal hospital survey and construction act; later Dr. William B. Meister, colonel, U. S. Army (retired), was employed to administer the act for the territory.

The total expenditure by the health department during the year was $1,942,954.99, of which $487,846.56 came from federal funds. The president of the Board of Health was Dr. Charles J. Wilbar Jr.

GENERAL

Florida Cited for Progress of Health Program.—Florida's public health program has been recognized by the Commonwealth Fund as making the "liveliest progress" of the six states receiving financial aid from the fund last year. The other states were Tennessee, Mississippi, Oklahoma, Louisiana and Kentucky. Florida now has sixty-two counties with local health departments.

Society for Prevention of Blindness—The National Society for the Prevention of Blindness, Inc., will hold its annual conference at the Radisson Hotel, Minneapolis, April 5-7. Subjects under discussion include public health responsibility for eye health, vision education, organizing the community for sight conservation, industrial eye care, scientific advances in prevention of blindness and education of the exceptional child.

Resolution Approves Nurse Anesthetists.—The Board of Regents of the American College of Surgeons, at a meeting on February 22, adopted a resolution commending the services of nurses who have had special training in the administration of anesthetics and recommending the continuance of training courses in this field for nurses. The American College of Surgeons is of the opinion that, in view of the inadequacy in number of physician anesthesiologists and the splendid record of achievement of nurse anesthetists, institutions engaged in the training of nurses for this purpose should be encouraged to continue their program.

The Louis Livingston Seaman Fund.—The New York Academy of Medicine announces the availability of the Louis Livingston Seaman Fund for the furtherance of research in bacteriology and sanitary science. There is $1,200 available for assignment in 1948. This fund is provided by the terms of the will of the late Dr. Louis Livingston Seaman and is administered by a committee of the New York Academy of Medicine under the following conditions: 1. The committee will receive applications either from institutions or individuals up to April 15, 1948. Communications should be addressed to Dr. Wilson G. Smillie, chairman of the Louis Livingston Seaman Fund, 1300 York Avenue, New York, 21. The fund will be expended only in grants for investigation or scholarships for research in bacteriology or sanitary science. The expenditures may be made for securing of technical help, aid in publishing original work and purchase of necessary books or apparatus.

FOREIGN

Germany's Only Cyclotron.—The only practical cyclotron in Germany, according to David Nichol, foreign correspondent for the *Chicago Daily News*, has stood idle at the Kaiser-Wilhelm institute for more than two years; its use, however, was authorized recently by the four power Allied Control Council in Berlin. The cyclotron has been repaired and is expected to begin operations in March to produce for German physicians radioactive substances for research in the study and treatment of certain diseases; also to conduct basic research on methods of handling and using radioactive isotopes. The Heidelberg cyclotron is small compared with the new cyclotron being developed in the United States. It is said to command a maximum of about 12,000,000 volts, while the newest American cyclotrons are many times as powerful.

Deaths

Henry Fernand Ader ⊕ New Orleans; born in New Orleans, March 7, 1884, Medical Department of Tulane University of Louisiana, New Yrleans, 1906; member of the city board of health; assistant surgeon in the U. S. Public Health Service during World War I, serving as director of the bureau of venereal diseases for the state of Louisiana; at one time on the faculty of the New Orleans Polyclinic; from 1927 to 1929 member of the faculty of the Presbyterian Hospital School for Nurses, teaching diseases of the ear, nose and throat; formerly visiting surgeon, ear, nose and throat service of the New Orleans Hospital and Dispensary for Women and Children, visiting surgeon chief of ear, nose and throat service at the Presbyterian Hospital; on the staff of the Charity Hospital; chief of the ear, nose and throat department of the French Hospital, where he died Dec. 28, 1947, aged 63, of myocarditis.

William Henderson Marshall ⊕ Flint, Mich.; born in Brampton, Ontario, Canada, March 24, 1874; Trinity Medical College, Toronto, Canada, 1901; past president of the Northern Tri-State Medical Association; past president and secretary of the Genesee County Medical Society; past president of the Michigan Trudeau Tuberculosis Society; fellow of the American College of Physicians; for six years a member of the Michigan State Board of Registration in Medicine; served during World War I; for fifteen years chief of the medical service at the Hurley Hospital, where since 1938 he had been director emeritus of the department of internal medicine, and where he died January 8, aged 73, of heart disease.

Thomas J. Crowe, Dallas, Texas; born in New York June 18, 1861; Homeopathic Medical College of Missouri, St. Louis, 1887; for many years secretary of the Texas State Board of Medical Examiners, of which he was a past president; past president of the Federation of State Medical Boards of the United States; served as a member of the National Board of Medical Examiners; formerly chairman of the city board of health; past president of the Texas Homeopathic Medical Association; affiliated with the Baylor University and Parkland hospitals; died January 1, aged 86, of heard disease.

Henry J. Gramling ⊕ Dousman, Wis.; St. Louis College of Physicians and Surgeons, 1899; past president of the Milwaukee County Medical Society; for many years a member and at one time secretary of the state board of medical examiners; formerly councilor of the twelfth district of the State Medical Society of Wisconsin; served during World War I; formerly on the faculty of Marquette University School of Medicine; affiliated with St. Luke's Hospital in Milwaukee, where he was chief of staff for many years; died Dec. 10, 1947, aged 73, of injuries received in an automobile accident.

Fred Taylor Andrews, Bay City, Mich.; Detroit College of Medicine and Surgery, 1918; member of the American Medical Association; served as director of the Bay County Health Department; formerly associated with the Fisher Body Division of the General Motors Corporation in Lansing; an officer during World War I; president of the Bay County Society for Crippled Children; affiliated with Mercy Hospital and General Hospital, where he died Dec. 21, 1947, aged 58, of carcinoma of the brain.

Robert E. Flood, Gladwin, Mich.; Louisville (Ky.) Medical College, 1897; served as director of the Tri-County Health Department; affiliated with the James Decker Munson Hospital in Traverse City; died Dec. 7, 1947, aged 77, of coronary occlusion.

John Andrew Freese, Detroit; Harvard Medical School, Boston, 1907; member of the American Medical Association; died recently, aged 71.

Samuel Friedman ⊕ New York; Bellevue Hospital Medical College, New York, 1895; member of the National Gastroenterological Association; died Dec. 14, 1947, aged 73, of coronary thrombosis.

Edwin Motley Fuller ⊕ Bath, Maine; Medical School of Maine, Portland, 1904; member of the New England Roentgen Ray Society; fellow of the American College of Surgeons; instrumental in the founding and president of the medical staff of Bath Memorial Hospital; died Dec. 2, 1947, aged 67

William Henry Gambill, Centralia, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910; member of the American Medical Association; served during World War I; past president of the Marion County Medical Society and the Centralia Township High School Board; affiliated with St. Mary's Hospital; served as chairman of the advisory board of the Illinois State Department of Conservation; died Dec. 14, 1947, aged 65, of coronary thrombosis.

Sidney Britten Goff ⊕ Eaton Rapids, Mich.; Rush Medical College, Chicago, 1931; served during World War II; died suddenly, Dec. 27, 1947, aged 48.

Mark M. Kerr, Miami, Fla.; American Eclectic Medical College, Cincinnati, 1894; died recently, aged 87.

Robert Edward Longino, Biloxi, Miss.; University of Nashville (Tenn.) Medical Department, 1901; formerly state sanitary inspector and health officer of Coahoma County; died Dec. 18, 1947, aged 69.

William Major ⊕ Peoria, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; past president of the Peoria Medical Society; affiliated with Proctor Hospital; died in St. Francis Hospital Dec. 24, 1947, aged 74, of carcinoma of the urinary bladder.

Gottlieb Joseph Marum ⊕ Greenville, Miss.; Universität Köln Medizinische Fakultät, Köln, Prussia, Germany, 1919; died Dec. 19, 1947, aged 54, of heart disease.

Gilbert Lewis McBee ⊕ Pendleton, Ore.; University of Oregon Medical School, Portland, 1926; fellow of the American College of Surgeons; past president of the Umatilla County Medical Society; member of the board of education in 1946 and 1947; affiliated with St. Anthony's Hospital, where he died Dec. 22, 1947, aged 45, of carcinoma.

Robert Lyness McCready ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1907; formerly professor of gynecology and obstetrics at the New York Polyclinic Medical School and Hospital; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; for many years affiliated with the Lenox Hill Hospital; died Dec. 14, 1947, aged 63, of cerebral hemorrhage.

Thomas Edward McGurk ⊕ Cape Girardeau, Mo.; St. Louis University School of Medicine, 1925; served on the staffs of the Missouri Pacific and St. Mary's hospitals in St. Louis; died Dec. 1, 1947, aged 45, of injuries received when his automobile struck a bridge abutment.

Florence Jess Correll McKenna, Los Angeles; State University of Iowa College of Medicine, Iowa City, 1910; died Dec. 22, 1947, aged 60, of cerebral hemorrhage.

Ocy May Crawford Johannes McKinley ⊕ Cleveland; University of Pittsburgh School of Medicine, 1926; a member of the board of trustees of Booth Memorial Hospital and the Woman's Hospital, where she died Dec. 17, 1947, aged 51, of carcinoma of the cervix uteri.

William Henry McLaughlin, Providence, R. I.; Dartmouth Medical School, Hanover, N. H., 1894; member of the American Medical Association; served on the school committee; affiliated with St. Joseph's Hospital; died Dec. 6, 1947, aged 78, of valvular heart disease.

Philip Howard Pettay, Flushing, Ohio; Starling-Ohio Medical College, Columbus, 1910; member of the school board; served as a physician for the Baltimore and Ohio Railroad; affiliated with the Martins Ferry (Ohio) Hospital; died recently, aged 71, of cerebral hemorrhage.

Eleanor L. Scull, Naples, Fla.; Woman's Medical College of Pennsylvania, Philadelphia, 1898; died Dec. 18, 1947, aged 81.

Daniel Joseph Sullivan Manchester, N. H.; Tufts College Medical School, Boston, 1916; fellow of the American College of Surgeons; died Dec. 16, 1947, aged 56.

Harvey E. Tucker, Lee's Summit, Mo.; Eclectic Medical University, Kansas City, 1901; retired druggist; died Dec. 9, 1947, aged 80.

Recent Researches On Synthetic Antihistaminics

Professor Pasteur Vallery-Radot's service at the Broussais Hospital conducts research on allergy and synthetic antihistaminic drugs. After conducting experiments, Drs. B. Halpern, J. Hamburger and S. Cruchand have reported that previous injection of 3,277 R.P. (N-(beta-dimethylamino- - Methyl -ethyl) phenothiazine) prevents, in 100 per cent of cases, acute pulmonary epinephrine-induced edema in rabbits. When given following the onset of edema, the drug appears curative. This same effect was noted in rabbit lung edema induced by chloropicrin (a war gas, trichloronitromethane) in which the drug appeared equally curative. Study of the use of the drug against other war gases is continuing.

In studies with the same drugs, Halpern and Laubsher reported that in 8 of 10 patients with allergic conditions there was an extremely great increase in capillary resistance beginning one to two hours after injection and persisting up to forty eight hours. In *nonallergic* patients the antihistaminic drugs did not appruciably modify capillary resistance.

Drs. Halpern, Perrin and Dews reported work on the local anesthetic powers of certain antihistaminic agents. They reported that compounds 3,300 R.P. and 3,376 R.P. show local anesthetic power four to six times greater than that of cocaine. They concluded from this that certain local effects of these drugs may be attributed to their anesthetic rather than their antihistaminic properties.

Streptomycin

At the Hospital *for* Sick Children, Professor R. Debre has instituted routine streptomycintherapy for tuberculous meningitis in children comprising one week of 100,000 units of the agent per kilogram of body weight per day parenterally plus two intrathecal injections of 50,000 to 100,000 units. After the first week, the patient receives 50,000 units per kilogram per day until cured. Treatment is suspended only after the disappearance of all pathologic signs. In 5 children with neurosurgical complications, surgical intervention disclosed a leptomeningitis or a pachymeningitis. A sixth child had a large tubercle near the chiasma. Operative intervention was highly successful in 2 cases. Early diagnosis was considered of utmost importance in predetermining the result of treatment. Of 100 children treated by Professor Debre, 46 have been successfully cured.

Ch. Mattei, Marseilles, presented results of treatment of 130 patients with streptomycin. Among these, of 22 cases of serious tuberculous laryngitis, 4 recovered and 17 were greatly improved. Of 20 patients with tuberculous meningitis, 17 recovered and 3 died. Pulmonary cavities associated with miliary or other tuberculosis closed rapidly during the course of intramuscular treatment with streptomycin. Relapses among all patients were frequent when insufficient dosage was employed. The author believed that neurotropism might well be responsible for the frequent appearance of neurologic complications from use of streptomycin. Such accidents were compared with similar complications which occur during gold therapy.

Congresses

The twelfth Congress of French-Speaking Pediatricians is scheduled in Paris from May 10 to 15, 1948 with Professor Edmond Lesne, member of the National Academy of Medicine, presiding. Subjects on the program include (1) toxic syndrome of nurslings: (A) etiologic, pathologic and therapeutic study by J. Levesque, Paris; *(B)* biologic study by Professor Fanconi, Zurich; (2) bronchial dilation in children: *(A)* anatomic and radiologic study, R. A. Marquezy and P. Renault, and (3) disorders of the function of speech in children, C. Launay, Paris. Full information may be obtained by corresponding with the general secretary, Dr. A. Marquezy, 16 Avenue Georges V, Paris (8).

The Congress of Longevity will be held under the auspices of the Vittel Medical Society at Vittel, June 12-13, 1948, with P. Joannon, professor of hygiene and preventive medicine at the Paris Faculty, presiding. Principal items of discussion relate to adult hygiene and the physiopathology of senescence, diseases of middle and old age, and improvements of sanitary and social hygiene measures necessary to extend life expectancy. The congress has been divided into several sections, which include (1) biology and clinics, (2) hygiene and general therapeutics and (3) statistics and sociology. Communications regarding the congress should be addressed to the general secretaries, Dr. Boigey at Vittel (Vosges), or Professeur Agrege M. Deparis, Laboratory of Hygiene of the Paris Faculty of Medicine, 21 Rue de l'Ecole de Medecine, Paris.

MADRID

(From Our Regular Correspondent)

Jan. 12, 1948.

The Midbrain-Pituitary Regulation of Carbohydrate Metabolism

At the Digestive Pathology and Nutrition Congress held in Spain, Dr. J. Andreu Urra, professor at Seville University spoke on The Midbrain-pituitary regulation of carbohydrate metabolism. He summarized his research since 1935, which was started in collaboration with Grünthal and Stryeck, studying the physiology of the midbrain-pituitary region. He mentioned the experimental and clinical facts which proved the part of the midbrain in the regulation of carbohydrates, saying that for the time being this regulation cannot be localized in any well defined cell group and accepting Hess's two anatomicophysiologic zones: the ergotrope, or sympathetic, and the trophotrope, or parasympathetic. While the posterior lobe of the pituitary has little or no importance as regards carbohydrate metabolism, the anterior lobe intervenes decisively, exercising its action through the various factors whose unity or plurality is still not clear.

The author and his collaborators have not been able to prove any variations in the regulation of glycohemia by acting through the optic midbrain-pituitary system. Finally, studying the main arguments in favor of the insular pathology of diabetes, he expressed the opinion that the pituitary factors are fundamental in this conection and that "in diabetes mellitus we must always accept the existence of an insulin deficiency, which is surely constitutional, and whose manifestation in the form of diabetes will be easier understood when to the pancreatic failure there is added a pituitary decompensation." In the field of therapeutics he advised going on with radiotherapy of the pituitary. In his experience the gonadal hormones have proved useless. *This report of Professor Andreu's school enhances the reputa*tion of the Seville Faculty of Medicine and is a tribute to the school of Professor M. Banuelos (Valladolid), where Dr. Andreu was trained.

National Cardiology Congress

The second National Cardiology Congress was held in Barcelona Dec. 11-14, 1947. The inaugural session was held in the assembly hall of the Royal Academy of Medicine, the old chair ofanatomy in which the famed Ginbernat once taught. In the audience were the civil governor of Barcelona, the president of congress, Professor A. Pedro y Pons, Dr. J. Framis de Mena, secretary of the Organizing Committee of the congress, and other notable persons. Dr. A. Crespo Alvarez lectured on the social aspect in diseases of the circulatory system and suggested regulations for the Spanish Cardiology Society and the campaign to help patients studied jointly by the members of the committee of the society.

On December 12 at the Doctors' Club, Professor L. Trias de Bes, director of the Infectious Diseases Hospital of Barcelona, read the first paper, on "Acute and Subacute Endocarditis." The report was warmly applauded in tribute to the author and his collaborators: Professor J. Sanchez Lucas, author of a complete anatomicopathologic study of endocarditis; Dr. Foz Tena, who investigated the bacteriologic aspects of endocarditis; Dr. Gras Riera, entrusted with the biologic aspects, especially of the plasmatic syndrome, and Dr. Cabre, who studied the dermatologic features. They came to the conclusion that there are two types of endocarditis of slow malignant evolution: (1) nonbacteremic, in which prognosis is more serious and which the authors suspect may be the evolutive malignant rheumatic endocarditis mentioned by some classic authors, and (2) bacteremic, including all forms of bacterial endocarditis of a subacute nature, whatever the germ that produces them. The evolution of each of these types is totally different, since the latter responds well to treatment with antibiotics while the former is nearly always fatal. Drs. J. Jimenez Diaz, A. Pedro y Pons, M. Soriano Jimenez, J. Gilbert Queralto, M. Beltran Baguena, T. Alday, J. Lamelas, F. Vega Diaz and many others took part in the debate on this report. In the afternoon Dr. Juan Lopez Brenes, a collaborator of Professor C. Jimenez Diaz, read a report on "Myocardial Infarct," in which he set forth his wide experience of the subject with electrocardiographic documentation. This report was also discussed by Drs. Adrio, Azpitarte, Vela, Benot Lozano, Bozal, Gonzalez Suarez, Codina Altes, Pijoan, Bravo, Clavera, Juncadella, Cornella, Soriano, Ciscar, Balcells, Cuellar, Duque Sampayo, Ortiz, Perez Gonzalez, Vega Diaz, and Roda. On December 13 Dr. A. Azpitarte from Granada read the third report on "Acute Tachycardias." The author reviewed all aspects of tachycardiac paroxysmal arrhythmias. In the afternoon a lecture was given by Dr. C. Jimenez Diaz, of the Madrid Faculty of Medicine, on "Arterial Hypertension." He submitted a report on the subject at the First National Cardiology Congress three years ago. After this a lecture was given by Dr. J. Lamelas, head of the cardiology department of the Valdecilla (Santander) on "Cardiopathies and Pregnancy." Later the Spanish Cardiology Society held a meeting at which Dr. J. Lopez Brenes spoke of the work done during the last three years and the financial difficulties which had to be overcome. The committee was then reelected for the next three years. The number of members attending the congress was one hundred and sixty-eight, besides one hundred and twenty-five collaborators. Visits were made to the National Museum of Montjuich, to the "Spanish Village" of Barcelona (a quarter especially devoted to displaying the customs and dresses of the various Spanish regions), a gala performance at the Liceo theatre, receptions and a farewell lunch at the Windsor Restaurant, where Profesor A. Pedro y Pons again spoke, wish them farewell in a few stirring words. The second National Cardiology Congress was an immense success.

The Spanish Journal of General and Applied Psychology

A new journal, entitled *Revista de Psiocologia General y Aplicada*, has just started publication in Madrid under the editorship of Dr. Jose Germain, who was director of the National Institute of Psychotechny until the end of the civil war. The object of the review is to present psychologic questions in all their amplitude, from those touching on philosophy to their more concrete applications in medicine and pedagogy, industry, and economic and social sciences. The first three issues of the new journal have already appeared.

BELGIUM

(From Our Regular Correspondent)

Liége, Feb. 18, 1948.

Intoxication by Aromatic Hydrocarbons

In the Belgian review of Social and Occupational Medicine Merlevelde, who is connected with a plant manufacturing chemical products, explains the present status of intoxication by hydrocarbons. His studies of the physiopathology of amino derivatives show that they exert a special action on the blood and produce anemia. They act equally on the nervous system and skin and secondarily on the bladder. Merlevelde does not limit himself to a report on the classic signs of poisoning by aniline; he investigated variations in the iron content of the plasma; he has studied the action of the aromatic products on the sedimentation speed and has investigated the importance of ascorbic acid on these poisonings. He has established that the resistance of the organism to benzene is increased by prophylactic administration of ascorbic acid. Merlevelde has verified these factors in workers who are exposed to aromatic products and their derivatives, and he has completed his investigations by experiments on guinea pigs. It seems that ascorbic acid acts as an antidote to these toxic substances.

Merlevelde takes up the question of the treatment of aniline poisoning, the methods of chemical detection and the various measures of technical and personal prophylaxis which he found expedient to employ.

Epidemic of Oil Pustules

Malter presented before the Belgian Society of Occupational Medicine an interesting contribution on lesions caused by industrial oil. He observed a veritable epidemic of pustules in different metallurgical factories in the region of Liége. This disorder appeared, particularly during the war period, due to the use of oils of inferior quality or the reuse of oils. Malter describes the industrial operation which gives rise to these disorders with the passing and repassing of the oil from the machine to the reservoir. He shows how this oil becomes infected by contact with skins previously infected with staphylococcic lesions. Specimens of oil obtained at the level of the machines revealed that they contain more than 90,000 particles of iron per cubic millimeter and staphylococci in large numbers.

In reviewing the literature, Malter thinks the authors have not considered all the factors in this disorder. In his opinion it is necessary to consider the mechanical factor due to the presence of metallic particles, a chemical factor which varies according to the nature of the oils used (mineral oils, coal oils or vegetable oils), an infectious factor and finally a human factor. He thinks that oily chemical disinfection of the oils by some nonirritating agent can give complete satisfaction.

Biopsy of Gastric Mucosa Under Gastroscopic Control

At the Belgian Society of Gastroenterology, Carmena D'Almeida of Paris demonstrated that a flexible biopsy forceps can be introduced simultaneously with a gastroscope that has an improved optic attachment, the entire apparatus being enclosed in a thin rubber cover The forceps is guided by silk thread traction under visual control. Specimens obtained will permit distinction between certain benign and cancerous tumors; and this will be a guide for more adequate therapy: It will be interesting to know the histologic aspect of the antral mucosa in pernicious and other anemias; in benzene gastritis and in the gastritis of arc welders:

Vision and Tobacco

Before the Society of Legal Medicine of Belgium, Hambresine and Schepens pointed out that amblyopias due to tobacco were frequent in Belgium during the war and that in the invaded and besieged regions one still finds smokers with diminished vision. Various authors think that the lesion in question is due to an intoxication due to both alcohol and tobacco. The only absolute diagnostic element is a peripheral scotoma which can be easily seen by means of the screen of Bjerrum. This scotoma characteristically presents one or two or even more extremely dense zones. The constituent of tobacco that provokes this visual disturbance is not known. The treatment is simple. It is sufficient to abstain from tobacco, but often improvement is not evident until the patient has abstained from tobacco for several weeks.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, March 13, page 796

BOARDS OF MEDICAL EXAMINERS

ARIZONA:* Examination. Phoenix, April 6-7. Endorsement. Phoenix, April 10. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

Arkansas:* *Examination.* Little Rock, June 3-4. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic:* Little Rock, June 3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Oral.* San Francisco, June 5-6; Los Angeles, Aug. 7-8. *Written Examination.* Los Angeles, Aug. 9-12. *Oral and Clinical Examination for Foreign Graduates.* San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

Colorado:* *Examination.* Denver, June 21-23. Final date for filing application is June 5. *Endorsement.* Denver, April 6. Final date for filing application is March 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

Connecticut:* *Examination.* March 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic Examination:* Derby, March 9-10. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

Delaware: *Examination.* Dover, July 13. *Endorsement.* Dover, July 22. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

HAWAII: Examination. Honolulu, July 12-15. Sec., Dr. S. Doolittle, 881 S. Hotel St., Honolulu.

Idaho: Boise, July 13-15. Sec., Bureau of Occupational Licenses, Miss Estella S. Mulliner, 355 State House, Boise.

Illinois: Chicago, April 6-8. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Springfield.

Indiana: *Examination.* Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

Kansas: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

Kentucky: *Examination.* Louisville, June 16-18. Sec., Dr. P. E. Blackerby, 620 S. 3d St., Louisville.

Maryland: *Medical Examination.* Baltimore, June 15-18. Sec.-Treas., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, June 15-16. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MINNESOTA:* Minneapolis, April 20-22. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul.

Mississippi: Jackson, June 1948. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

Missouri: *Examination.* St. Louis, May 24-26. Final date for filing application is April 24. Exec. Sec., Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

Montana: Helena, April 5-7. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

Nebraska:* *Examination.* Omaha, April 5-7. Dir., Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln 9.

Nevada: Carson City, May 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Jersey: *Examination.* Trenton, June 15-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

North Carolina: *Endorsement.* Pinehurst, May 4. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

Ohio: *Endorsement.* Columbus, April 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma:* Oklahoma City, June 2-3. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Endorsement.* Portland, May 7-8. Final date for filing application is April 23. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia & Pittsburgh, July. Act. Sec., Bureau of Professional Licensing, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Rhode Island:* *Examination.* Providence, April 1-2. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Written Examination.* Columbia, June 21-23. *Endorsement.* April 5. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA:* Pierre, July 20-21 * Sec., Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Tennessee:* *Examination.* Memphis, March 24-25. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Utah: *Examination.* Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: *Examination.* Richmond, June 18-19. *Endorsement.* Richmond, June 17. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., Roanoke.

West Virginia: Charleston, April 5-7. Comm., Public Health Council, Dr. N. H. Dyer, State Capitol Bldg., Charleston.

Wisconsin:* Milwaukee, June 29-July 1. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

Wyoming: *Examination.* Cheyenne, June 7. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arkansas: Little Rock, May 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

District of Columbia: *Examination.* Washington, April 19-20. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington.

Florida: *Examination.* June 5. Final date for filing application is May 23. Sec., Mr. M. W. Emmel, Univ. of Florida, Gainesville.

Iowa: Des Moines, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, May 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

Minnesota: *Examination.* Minneapolis, April 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, May 4-5. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, March 21. Sec., Miss Marguerite Kilkenny, 114 E. Marcy, Santa Fe.

Oklahoma: Oklahoma City, April 2. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, June 19. Sec., Basic Science Examining Committee, Mr. C. D. Byrne, Univ. of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, June 4-5. Sec., Dr. G. M. Evans, 310 E. 15th St., Yankton.

Wisconsin: *Examination.* Madison, April 3. Sec., Dr. W. H. Barber, Scott & Watson Sts., Ripon.

Medical Motion Pictures

FILM REVIEW

RETURN TO ACTION. 16 mm., black and white, sound 725 feet (1) reel, showing time nineteen minutes. Produced in 1946 for the British Ministry of Labour, London, England. Procurable on loan from British Information Service, 30 Rockefeller Plaza, New York 20 or Local Office.

This excellent film on vocational rehabilitation describes the extremely well-organized program which has been developed in England for the vocational rehabilmtation of disabled persons. The work at the Vocational Rehabilitation Center at Egham is shown; here successive groups of disabled men are trained vocationally to assume again their places in civilian life. The script centers around the progressive rehabilitation of a man whose lower extremity was amputated and who proceeds from the stage of despair because of his disablement through successive stages to reemployment. First he goes to Egham for vocational rehabilitation, then to the government training center at Stowe and finally to the Devon residential training center. At last he is placed in a suitable posintion in industry and happily reemployed.

The filming is of good quality, the narration is excellent and the picture will interest anyone primarily concerned with rehabilitation of the seriously disabled. While there is little of a medical nature in this film physicians should see it because it indicates clearly how modern methods of industrial and vocational rehabilitation can restore even seriously handicapped persons. This Film could well be used as a supplement to the several excel-

lent films on physical rehabilitation which have been pre•

lent films on physical rehabilitation which have been prepared recently.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

*Propylthiouracil in Treatment of Hyperthyroidism. E. P. McCullagh, R. E. Hibbs and R. W. Schneider.—p. 545.

Use of Pyribenzamine in Prevention of Histamine-Induced Gastric Acidity and Headache and in Treatment of Hypersensitiveness to Cold. E. L. Perry and B. T. Horton.—p. 553.

Application of Immunologic Principles to Management of Hay Fever, Including Preliminary Report on Use of Freund's Adjuvant. Mary H. Loveless.—p. 559.

Rheumatoid Spondylitis. D. G. Pugh.—p. 568.

Anemia and Diaphragmatic Hernia.—Ritchey and Winsauer review 41 cases of diaphragmatic hernia, the records of which were found either in the medical records of the Indiana University Medical Center or in the files of the roentgenologic department. There were 27 females and 14 males, which is in accord with the accepted predominance of females over males. Thirty of the cases showed herniation of the stomach alone, the other 11 cases involving herniation of the stomach plus other abdominal viscera. The authors detected a secondary anemia in 11 of the 41 cases. This incidence of anemia is not as high as in some reported series, but is higher than in a number of other series. It tends to substantiate the fact that anemia in diaphragmatic hernia is often found as part of the disease and that it does not have to be associated with a history of gastrointestinal bleeding.

Prolonged Incubation: Infectious Hepatitis and Homologous Serum Jaundice.—Aycock and Oren show that in neutralization and protection tests in a number of virus infections having different incubation periods a portion of the animals inoculated with mixtures of virus and immune serum develop the disease following incubation periods that are longer than those resulting from inoculation with virus and nonimmune serum. Prolongation is proportionate to the length of the incubation periods of each of the several diseases. The degree of prolongation of the incubation period of homologous serum jaundice over that of infectious hepatitis is equivalent to that observed in other neutralization or protection tests. In the light of this epidemiologic principle it is suggested that the difference in the incubation periods of infectious hepatitis and homologous serum jaundice is due to differences in the manner of transmission of a single virus which involve admixture of virus with antibodies. The shorter incubation period, generally regarded as characteristic of infectious hepatitis, occurs when transmission of either of the two types of jaundice is accomplished by intranasal or oral administration or by contact (serum-free virus). The longer incubation period, regarded as characteristic of homologous serum jaundice, follows the transmission of either of the types of jaundice by the injection of serum containing virus. It is postulated that the prolongation of the incubation period of homologous serum jaundice over that of infectious hepatitis is the result of partial neutralization of the virus by admixture with serum containing antibodies of either the donor or recipient patient or by the in vitro action of serum that contains antibodies on the virus

Caronamide and Penicillin in Bacterial Endocarditis.—Boger and his co-workers found in preliminary clinical investigations that penicillin plasma concentrations were enhanced threefold to sevenfold by the oral administration of caronamide, and no serious toxic manifestations were observed. They treated a woman aged 51 with subacute bacterial endocarditis due to a strain of streptococcus resistant to penicillin and streptomycin by the intramuscular administration of penicillin and the oral administration of caronamide. In this patient, as in a control in whom the two substances were administered simultaneously, there was good correlation between the concentration of caronamide in plasma and the enhancing effect on concentrations of penicillin in plasma. The authors stress that even when the dosage employed is measured in millions of units per day, the plasma levels of penicillin can be elevated by the administration of caronamide. The effect of caronamide in the treatment of this patient was equivalent to the injection of additional millions of units of penicillin.

Propylthiouracil in Hyperthyroidism.—The use of propylthiouracil over a fourteen month period convinced McCullagh and his associates that the drug is decidedly superior to thiouracil in the treatment of hyperthyroidism. In 218 patients treated for an average of eight months and in some treated as long as fourteen months no cases of agranulocytosis were seen. Three minor reactions occurred, and four other reactions required the cessation of treatment. The drug is effective in the control of hyperthyroidism of all types except possible instances of acute crisis, in which its action is too slow. The hyperthyroidism of acromegaly may also be an exception. An effective dose in more than 95 per cent of patients has been 300 mg. per day. A smaller dose is effective in many cases; a larger dose has been required in less than 4 per cent. Iodine in doses as high as 30 mg. per day may be used concurrently with propylthiouracil. It will eliminate the thrill and bruit in diffuse glands and does not hinder the action of propylthiouracil.

"Mal del Pinto;" Treatment by "Mapharsen.—Varela and Avila say that according to a 1934 census there were 270,049 persons with pinta, mal del pinto, or carate in Mexico. They estimate that in the rest of the Western Hemisphere, chiefly Colombia and Venezuela, there are approximately 500,000 persons infected with this disease. In 1938 a treponeme which has been designated as Treponema carateum, or Treponema herrejoni, was discovered in the lesions and lymph nodes of patients with pinta. The authors were able to grow T. carateum in anaerobic mediums, or on the chorioallantoic membrane, or in the yolk of fertilized eggs. The authors studied 805 patients with regard to the history of pinta in their parents. They found a somewhat higher incidence of pinta in persons whose parents had the disease than in those whose parents were free from it. Pinta usually begins with spots of desquamating erythema chiefly on the uncovered parts of the body. Later dyschromic lesions appear, which may be red, pink, blue and white. The red and blue lesions are distributed all over the body, whereas the white spots are mainly found on shoulders, elbows, hand, knees and feet. In nearly half of the patients pruritus exists during the dyschromic stage. Wassermann and Kahn reactions are frequently positive. The authors used oxophenarsine hydrochloride ("mapharsen") for treatment, administering 0.04 Gm. twice a week. The total number of injections was usually fifteen, although some were given only five. Several hundred patients were treated, but only 66 were observed for periods as long as a year. In 6 the lesions were not changed in aspect, and in the others only part of the hyperchromic spots disappeared.

Plague.—Ruegsegger and Gilchrist believe that an antiplague program should include (*a*) quarantine and isolation, (*b*) control of rodent populations, (*c*) emphasis on pulicidal measures, and (*d*) prophylaxis of the individual contacts. Effective therapeutic agents are now available. Serums have been developed, but the objection to all serums, expense and necessity for parenteral administration, applies to antiplague serum and may conceivably be its limiting factor. The sulfonamide drugs, particularly sulfadiazine, constitute the most effective therapeutic agents in plague. Suggestive confirmation of the curative effect of the sulfonamide compounds in human infections is accumulating. Streptomycin has been shown by Wayson and McMahon to be effective in curing plague in guinea pigs. The human clinical application awaits confirmation. Chu in discussing the current situation with regard to plague in China reported a unique incident which suggests a more hopeful prognosis for victims of pulmonic plague. A physician contracted pneumonitic plague while engaged in transferring virulent cultures in the laboratory. Sulfadiazine therapy was instituted in full doses on the second day of symptoms after the diagnosis had been confirmed culturally. On the fourth day and for several days thereafter streptomycin was also administered. The patient made an uneventful and complete recovery.

Penicillin in Infectious Syphilis.—Joseph and his associates review observations on 263 patients with syphilis who were treated with penicillin in four different dosage schedules. There were 168 patients who received 2,400,000 Oxford units of sodium penicillin in aqueous solution, 20,000 units every three hours for fifteen days; 38 received 4,800,000 units, 40,000 units every three hours for fifteen days; and 47 had 9,600,000 units, 80,000 units every three hours for fifteen days. The fourth group, comprising 10 patients, received 9,600,000 units of calcium penicillin in peanut oil and beeswax, given by a single daily intramuscular injection of 600,000 units for sixteen consecutive days. Patients were followed clinically and serologically from one to eighteen months after treatment. The study is presented to indicate a trend that higher dosages are probably advisable. It is also suggested that the general practitioner use penicillin as an adjunct to regular arsenical and bismuth therapy, rather than alone.

Wilms's Tumor.—According to Esersky and his associates increasing reports on Wilms's tumors in adults indicate that they are not as rare as has been presumed. Fifty-three cases have been reported previously, and to this number the authors add 3 cases of their own. The first patient, a man aged 47, died before the true nature of the disease had been recognized. Necropsy revealed an embryonal sarcoma (Wilms's tumor) of the right kidney with metastases to the liver, lungs and vertebrae, coronary thrombosis, bronchopneumonia and other disorders. The second case concerned a woman, aged 33, who was subjected to surgical treatment with the diagnosis of degenerating renal neoplasm. A nephrectomy was done on the left side. Examination of the surgical specimen established the diagnosis of malignant teratoma of the kidney (Wilms's tumor) with direct intrapelvic, extrarenal and intravascular invasion. The patient died two months after the operation. The third patient, a woman aged 24, was subjected to nephrectomy. An embryonal adenocarcinosarcoma of the kidney (Wilms's tumor) was found. The patient was given postoperative roentgen therapy and was still alive three years after the operation. The prognosis is unfavorable in this type of tumor. A patient with an unusually large renal mass and a high elevation in temperature, without evidence of urinary infection, should cause one to be suspicious of the possibility of Wilms's tumor

Control of Urinary Tuberculosis.—The study described by Slotkin was undertaken to determine whether there existed a more rapid and permanent control of inoperable or bilateral renal tuberculosis than the present therapeutic methods offered. With the advent of streptomycin such a control seemed to be available. Tubercle bacilli have a tendency to develop resistance against streptomycin. Mycobacterium tuberculosis has a protecting waxy cell wall. The same condition exists in Mycobacterium leprae. Long before the advent of antibiotics the author had conceived the idea that if a substance could be found to dissolve the protecting waxy wall, the process involved in inhibiting the growth might be enhanced. Knowing the existence of the same process in M. leprae, the oil of chaulmoogra and its derivative esters were experimented with in a few cases. After describing in vitro and animal studies on the effect of chaulmoogra oil on the sensitivity of Mycobacterium phlei to streptomycin, the author describes clinical observations on 6 active cases of inoperable and bilateral renal tuberculosis with secondary vesical symptoms. In the first 3 cases treatment was with the regular oil of chaulmoogra; later "moogrol," a more refined oil (a mixture of the ethyl esters of the fatty acids of the chaulmoogra series of oils) which is painless, more readily absorbable and nonirritating, was used. Each patient received 1 cc. of the oil intramuscularly daily for three days, then the dosage was increased to 2 cc. for four days. On the seventh day, the patient received 1 cc. of the oil and 1 Gm. of streptomycin. The treatment period lasted thirty days. The antibiotic is added to 16 cc. distilled water or sodium chloride solution and administered in eight doses of 2 cc. each, every three hours. All patients were hospitalized but ambulatory. The clinical results of this "softening and conditioning process" warrant further investigation, not only in the urologic tract but in all types of tuberculosis.

Parathyroid Extract and Diuresis.—Moehlig and Abbott direct attention to the diuretic effect of parathyroid extract, which has been known for some time. They present 2 case histories which illustrate the favorable effect of parathyroid extract. First, in a man aged 54 oliguria developed following treatment with sulfadiazine and sodium bicarbonate. The patient began to pass increasing quantities of urine on the second day of treatment with parathyroid extract. The patient was given 2 cc. (200 units) of this extract by intramuscular injection on four successive days. On the fifth and sixth days he was given 1 cc. and 0.5 cc., respectively. After that, the drug was discontinued because of the striking improvement. Second, a woman aged 36 was hospitalized with generalized urticaria, edema and sporadic convulsions, attributed to the ingestion orally of four tablets (25,000 units each) of penicillin. Treatment with diphenhydramine ("benadryl") caused exacerbation of the symptoms, particularly the edema. Diuresis finally began, and the edema subsided after the second injection of 2 cc. of parathyroid extract. The authors stress that the diuretic effect is directly proportional to the degree that calcium is mobilized in the blood.

Factors Influencing Survival in Coronary Thrombosis.—Tredway studied cases of acute myocardial infarction in order to ascertain what prognostic guides may give information as to the immediate outcome of the attack. The data were obtained *only from* cases of classic myocardial infarction, the diagnosis being based either on clinical criteria and unequivocal electrocardiographic evidence or on observations at necropsy. The series consists of 54 patients, of whom 21 died and 33 survived the acute attack. On the basis of his survey Tredway regards the following manifestations presented by a patient with acute myocardial infarction to be of bad prognostic import as far as survival in that attack is concerned: a past history of diabetes; previous infarction; congestive failure or vascular disease other than hypertension; epigastric pain; dyspnea; tachycardia; a pulse pressure of 20 mm. of mercury or less; evidences of shock; manifestations of congestive failure; irregularities of rhythm, particularly auricular fibrillation; either an elevated blood urea nitrogen level or blood sugar determination in the absence of renal disease or diabetes; a prolonged auriculoventricular conduction time.

**Relation of Group Morale to Incidence and Duration of Medical Incapacity in Industry. K. Brodman and L. P. Hellman.—p. 381.*

Group Morale and Duration of Medical Incapacity in Industry.—The investigation of Brodman and Hellman was carried out on 600 employees of a mail order firm in New York. The relation between group influences and the duration of medical incapacity was investigated, using medical absenteeism as the measure of medical incapacity. No correlation was found between absence for long illnesses and lateness. However, in each quarter those departments in which employees were frequently absent for short illnesses were also those in which employees were frequently late. Since the frequent occurrence of lateness is a concomitant of poor morale, it appears that those departments in which employees are frequently absent for short illnesses are those in which the morale is poor. Medical incapacity is thus related to group morale. The data indicate that different work groups have dissimilar morale, that a person's work morale is decidedly influenced by the group in which he works and that group morale is intimately related to the occurrence and duration of short medical incapacities.

*Nutritional Status of Puerto Rican Rural Community in Relation to Its Dietary Intake. Una Robinson and R. M. Suárez.—p. 100.

Nutritional Status in Rural Puerto Rico.—The report by Robinson and Suárez deals with a survey of the nutritional status and dietary intake of a population sample in a rural community of Puerto Rico. Its purpose was twofold: (1) to determine the dietary intake and its adequacy and (2) to study the correlation of said intake with the nutritional status. The dietary studies showed that the diets were conspicuously low in calcium, vitamin A and riboflavin and that all other dietary essentials failed to measure up to the recommendations of either the National Research Council or to a more conservative standard elaborated for Puerto Ricans. These diets were conspicuously low in milk and yellow and green vegetables. Physical examinations revealed many signs of nutritional deficiencies. Sixty-one per cent of the subjects were more than 5 per cent underweight; 73 per cent had dental caries or had lost some teeth; 79 per cent had slight or moderate signs of vitamin A deficiency; 95 per cent, of riboflavin deficiency; 28 per cent, of nicotinic acid deficiency, and 48 per cent, of ascorbic acid deficiency.

Absorption of Penicillin Given by Mouth.—Stewart and May have tried to determine the relative importance of the factors governing the absorption of penicillin given by mouth, but made no attempt to treat actual infections; all the results were obtained in normal healthy adults. They found that in order to insure the best possible absorption, penicillin by mouth should be given on an empty stomach. The use of capsules gave results inferior to those obtained with the same dose in aqueous solution. The destructive effect of gastric acidity is only of importance when the p_H is less than 3. Most of the penicillin is absorbed in the upper part of the small intestine. Destruction of penicillin by penicillinase in the upper part of the digestive tract is negligible. Dextrose is a convenient source of energy which can be given with penicillin and often enhances the result. The most important factor influencing the absorption of penicillin seems to be the unexplained individual variations in the absorptive capacity of the intestine. The penicillin should be given in about 4 ounces (118 cc.) of a 5 to 10 per cent solution of dextrose, containing about 20 grains (1.29 Gm.) of sodium bicarbonate or citrate, before meals, and not less than three hours, preferably four hours, after the previous meal. The dose should be ten times as great as the dose of intramuscular penicillin that produces the blood penicillin levels required.

New Formation of Smooth Muscle in Lung. K. M. Bowden.—p. 623.

Fish Poisoning at Fanning Island.—Ross says that between February 1946 and April 1947 fish poisoning occurred in 95 persons in a population of 224 persons on Fanning Island in the central Pacific area. The symptoms of this poisoning are slow pulse, contracted pupils, numbness and sensation of tingling over the whole body, especially around the lips and at the fingertips. Gastrointestinal symptoms (epigastric pain, diarrhea and vomiting) are present in 75 per cent of cases. The symptoms are becoming more and more severe and nervous features more prominent. The recovery is extremely gradual, and weakness persists for several weeks. Cats, dogs and domestic ducks that are fed poisonous fish experimentally or accidentally develop ascending paralysis in eight to twelve hours, the paralysis lasting from three to five days. Ten different species of fish have already been classified as poisonous at Fanning. Prior to 1946 these fish were eaten without any ill effect. The areas in which the poisonous fish are caught correspond with places where the American army dumped war materials in July 1945. It is suspected that the plankton and algae as well as crustaceans and seaworms on which fish feed contain a poisonous principle emanating from deteriorating dumped war material. The effect of the poisonous agent at Fanning is similar to that of the poison isolated from sea plankton around San Francisco, where this agent was responsible for many cases of shellfish poisoning and was found to belong to the class of alkaloids.

*Primary Atypical Pneumonia. B. Knutsen.—p. 2099.
Peritoneal Irrigation in Anuria. B. Fretheim and O. Selvaag.—p. 2106

Primary Atypical Pneumonia.—Knutsen says that since Feb. 1, 1946, 86 certain cases and 24 probable cases of primary atypical pneumonia were seen at Drammen Hospital. In the course of a year the disease constituted over 37 per cent of the cases of pneumonia treated in the hospital. Most of the cases appeared as an epidemic in the fall of 1946. The disease was benign, with few complications but with protracted course. In the severest cases the cold agglutination titer continued high for weeks; in the mildest cases the titer fell rapidly. Penicillin or sulfonamide drugs were of no value except in a few cases with signs of bacterial complication. In 3 cases there was an erythema multiforme exsudativum, regarded as a complication of the primary atypical pneumonia, perhaps by activation of a virus. In 3 of the 4 samples of convalescent serum sent to him Eaton demonstrated neutralizing antibodies against the Eaton virus, indicating either present or past infection.

*Local Injections of Penicillin in Treatment of Adnexa. M. Roux and P. Monod-Broca.—p. 845.
*Role of Sewage Water as Disseminator of Virus of Poliomyelitis. C. Kling.—p. 848.

Penicillin in Treatment of Adnexa.—Roux and Monod-Broca treated 19 women who had salpingo-ovaritis with local injections of penicillin made at the level of the vaginal cul-de-sac. Eleven of the patients had an acute salpingitis characterized by a plastic reaction with bilateral painful soft swelling, mild rise of temperature and moderate leukocytosis. In 9 of these cases favorable results were obtained with five to six injections of 25,000 units of penicillin which were repeated every second day; complete recovery occurred in 6 patients, while the 3 remaining patients presented a small residual mass which subsided after three injections of "propidon" (Delbet's vaccine). Two patients with periuterine postpartum infection were therapeutic failures. Local treatment did not succeed in 2 additional patients with chronic salpingitis. Satisfactory results were obtained in 6 patients in whom an abscess that developed in the course of salpingitis was not amenable to any other treatment, general penicillin treatment included. In cases in which the sac of the abscess is accessible by the vaginal route, pus should be removed by puncture and penicillin should be injected into the cavity. Subperitoneal drainage may be employed in cases in which the sac shows an abdominal development, and penicillin should be introduced by means of a drain. If there is no suppurative sac or if it is not accessible, the injection should be made into the inflamed area around the adnexa. In periuterine infection local treatment with penicillin proved to be superior to general treatment with the agent and was effective when the latter failed. It is particularly indicated for periuterine lesions complicated by abscess.

Virus of Poliomyelitis in Sewage.—According to Kling, sewage water played an important part in the dissemination of the virus of poliomyelitis in two epidemics of poliomyelitis in two towns of Sweden during 1944. Sixty-three cases of poliomyelitis were observed in Katrineholm, a town of 11,570 inhabitants, i. e., a sick rate of 54.4 for ten thousand persons. Because of insufficient purification by filtration on sand, the sewage water contaminated the entire water system by which the drinking water was furnished to the population of this town. Fifty-three cases of poliomyelitis occurred in Halmstad, a town of 30,000 inhabitants, i. e., a sick rate of 17.6 for ten thousand. A sewage which apparently contained the specific agent caused contamination of the water which was furnished by one of the three systems of the town. Although experimental proof has not been obtained, the author believes that contaminated water which may be used by man for various purposes should be considered as one of the links which connects the sewage—into which the fecal ultravirus flows—with man who is susceptible to contamination.

Book Notices

Handbook of Diagnosis & Treatment of Venereal Diseases. By A. E. W. McLachlan, M.D., Ch.B., D.P.H. Third edition. Cloth. Price, $5. Pp. 375, with 160 illustrations. Williams and Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2. 1947.

This brings up to date the use of various therapeutic agents, especially penicillin, in the treatment of the various manifestations of syphilis and gonorrhea. Of the *362* pages in this book, the first 203 are devoted to syphilis in all its phases. Although some syphilologists might take issue with the author in the treatment of some phases of syphilis, especially the meager space he has given to fever therapy, on the whole the subject is well presented. The book is well illustrated with 160 pictures, twenty of these in color, and mostly photographs of the various manifestations of the diseases. The chapters are well organized, the subject matter well outlined and the book easy to read. Besides syphilis and gonorrhea other conditions commonly referred to the venereal disease department, such as lymphogranuloma inguinale, balanoposthitis, genital warts and paraphimosis, are briefly considered. As the title states, it is a handbook dealing with the diagnosis and treatment of veneral diseases and as such can be recommended to the busy practitioner and also the undergraduate medical student. To the general practitioner this book can be especially recommended.

The Cerebral Palsied Child and His Care in the Home. Prepared by Viola E. Caldwell, R.N., M.A. Staff Education for Nurses Engaged in Orthopedic Public Health Nursing. Cerebral Palsy Series: Revision of Pamphlet I. Paper. Price, $1. Pp. 196, with illustrations. Association for the Aid of Crippled Children, 580 Fifth Ave., New York 19, **1947**

This dissertation deals with cerebral palsy in education, medical aspects, special therapies, general hygiene and social implications; it is well organized, rather complete in its coverage and well printed. Some aspects of the problem are underemphasized, as for instance the convulsive diatheses of the children. On the other hand some of the practical therapeutic procedures employed in physical therapy and in the teaching of self help and speech are well handled. The appendix giving standard forms employed in functional examinations and illustrating the various types of apparatus and the bibliography are of definite value. This book does not offer any new material or basic contributions to the field, since it consists primarily of quotations and excerpts from various sources. Much of the subject matter is controversial, and unfortunately this fact is not always indicated in the text. As an informational handbook for orientation of public health or orthopedic nurses, it is to be recommended. However, it does not fulfil the need for an authoritative book on the subject of cerebral palsy.

Importancia biológica del potasio. Por el Dr. Vicente Hector Cicardo, profesor titular de física biológica de la Facultad de ciencias médicas de la Universidad nacional de La Plata. Paper. Pp. 254, with 20 illustrations. Librería y Editorial "El Ateneo," Florida 340, Córdoba 2099, Buenos Aires, 1947.

Professor Cicardo's monograph on the biologic importance of potassium is the most exhaustive written on this subject, as the 774 references discussed in the text testify. The book comprises sixteen chapters: 1, the origin and significance of potassium; 2, intracellular potassium; 3, potassium in the tissues; 4, extracellular potassium; 5, toxicity; 6, striated muscle and potassium; 7, cardiac muscle; 8, smooth muscle; 9, nerve; 10, central nervous system; 11, digestive secretions; 12, adrenals; 13, other glands of internal secretion; 14, shock; 15, anoxia, acid-base equilibrium, and 16, potassium in various pathologic conditions. On each of these subjects the author reviews the literature and presents the conclusions derived therefrom as well as from his own work.

Professor Cicardo's own work, presented in detail, was done mostly on frogs and includes cellular permeability to potassium and the influence of ions, specially of calcium; the influence of potassium on muscular contractions; the relation between acetyl choline and potassium, and the role of potassium in nerve transmission; the role of potassium in the mechanism of action of the adrenal glands. His experiments on the role of potassium in the production of shock were performed on dogs.

Although the role of potassium in the performance of all these biologic processes is undeniable, Professor Cicardo seems to have been carried away by his enthusiasm beyond the limits prescribed by the experimental facts. Professor Cicardo's theory of increased permeability of all cells in adrenal insufficiency is interesting and deserves attention.

Simplified Diabetic Manual with 163 International Recipes (American, Jewish, French, German, Italian, Armenian, etc.). By Abraham Rudy, M.D. Revised by Martin M. Nothman, M.D., Instructor in Medicine, Tufts College Medical School, Boston. Introduction by Dr. Frederick M. Allen. Fourth edition. Cloth. Price, $3. Pp. 216, with illustrations. M. Barrows & Co., Inc., 114 E. 32nd St., New York 16, 1947.

With the exception of the chapters devoted to the various menus, especially those concerned with the foods of the various nationalities, this book is too cursory to be helpful to the diabetic person or to the physician concerned with the disease. In the section devoted to "marriage in diabetes," for instance, charts indicate that diabetes is hereditary and yet the closing sentence states that "congenital diabetes is extremely rare." This is confusing to the layman. The chapter on insulin fails to make clear to the average reader the distinctions concerning the three now well known types, for he fails to be specific and sufficiently descriptive in his discussion concerning the time of administration and the actual length of the effect of the various insulins. For example, when writing on globin insulin he states "that one injection may be enough." When is it not enough? How can the reader judge? It is confusing too that the chapter on "diabetes in children" precedes those on "marriage in diabetes" and "diabetes and pregnancy," which two are followed by treatment of the elderly diabetic. The material could well be better arranged. This book is invaluable to one interested in menus but not especially helpful to those concerned with the progress made in treatment of diabetes.

Physical Medicine in General Practice. By William Bierman, M.D., Attending Physical Therapist, Mount Sinai Hospital, New York. With a Chapter on Medical Rehabilitation by Dr. Sidney Licht. Second edition. Cloth. Price, $8. Pp. 686, with 310 illustrations. Paul B. Hoeber, Inc., 49 E. Thirty-Third St., New York 16, 1947.

This carefully planned book not only covers the complete field of physical medicine but also has added interest by numerous clear illustrations for visual teaching. The theme is developed from simple subjects to those requiring more advanced knowledge of basic sciences. The chapter on climatotherapy and spa therapy gives a practical insight into the indications for these physical mediums. The chapters on heat, light and electricity reflect the broad experience of the author in research and use of these measures. The important details of massage, exercise and occupational therapy are included. Dr. Sidney Licht's excellent chapter on rehabilitation shows his realization of the importance of considering the patient as a total personality. Psychologic and physical factors are presented in their proper perspective. The paragraphs on paraplegia and amputations as well as those related to speech, vision and hearing are authoritative from the background of his experience as a medical officer in the recent war and as present consultant in the Veterans Administration. The transition through formal treatment to diversional and work therapy is well developed. In the last third of the book Dr. Bierman includes plans for departments of physical medicine and for treatment. Emphasis is given to professional responsibility, medicolegal problems, dangers and cautions. Diseases of the various systems are discussed in light of indications or contraindications for physical treatment. At the end of each chapter is a list of references for the benefit of readers who wish to pursue certain subjects in greater detail.

One wonders about the title of the book after reading it. Will the general practitioner be able to use this book for easy reference? There is no question but that it will be a useful volume for the physiatrist, physical therapist and occupational therapist. Other physicians with interest and groundwork in physical medicine will, no doubt, appreciate its subject matter. Perhaps, in justice to the author, one should quote from the preface: "I have attempted to emphasize those sections of physical medicine which the general practitioner may be reasonably expected to apply in his practice. I have also made reference to important therapeutic considerations which are beyond the scope of the general practitioner in order that he may become aware of them even though he cannot utilize them himself."

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

ALCOHOLISM AND HEREDITY

To the Editor:—Are there statistics to prove that the children of alcoholic persons are more apt to be imbeciles?

M.D., Monterrey, N.L., Mexico.

Answer.—Belief that alcoholism in man affects the germ plasm lacks substantiation. Since 35 to 40 per cent of alcoholic addicts come from families with epileptic, psychotic or feebleminded members, it is not surprising that the alcoholic persons themselves show a high incidence of these disorders, some of which are known to be hereditary. Excessive drinking cannot be expected to prevent their transmission. Boss (*Monatschr. f. Psychiat. u. Neurol.* **72:**264, 1929) showed that these defects do not appear more frequently in the children of unstigmatized alcoholic persons than they do in the general population.

Roe (*Quart. J. Stud. on Alcohol* **5:**378-393, 1944) reports convincing evidence against hereditary factors caused by alcoholism of parents. She compared adult adjustments of children of alcoholic parents to a control group of children of normal parents, both groups having been raised in foster homes. Significant differences were not found. Greater consumption of alcohol did not occur in the offspring of alcoholic parents than in the control group.

EPIPHYSIAL ARREST

To the Editor:—A boy now aged 12½ years was stricken by poliomyelitis at 2 years of age. His left leg was badly damaged and suffered the loss of the iliopsoas muscle, quadriceps muscle, the peroneus group and others. There is pronounced atrophy and shortening of the left leg of about 1¾ inches (4.5 cm.). The patient walks with a long leg brace (using the gluteus muscles). He is able to walk without a brace but is then more unsteady because of difficulty in locking the knee joint.

The main problem at present and for the future appears to be the difference in length of the lower extremities. This boy comes from a family of medium height, and probably he will not be exceptionally tall. His present height is 4 feet 11 inches (149.86 cm.). Now is probably the time to consider an epiphysial arrest on the unaffected leg. Although there are many reports available recommending this procedure I am led to believe that the reported incidence of deformities following this operation is quite high and discouraging.

Regan and Chatterton (*J. Bone & Joint Surg.* **28:**265 [April] 1946), although recommending the operation, report deformities in 4 of 36 persons with epiphysial arrest. Therefore supracondylar shortening of the femur on the good side done at the end of the growth period, although a more formidable operation, seems more logical and safe to me.

Please give an opinion and estimate the damage that can be done to the spine, which has to make up by compensatory lordosis for the unilateral shortening, if one waits with an equalization by supracondylar shortening until the end of the growth period or young adulthood has been reached?

M.D., Wisconsin.

Answer.—The choice of operative procedure in a case such as that described should be made on the basis of the surgical training and experience of the surgeon who is doing the work.

Opinions with regard to equalization of leg length by epiphysial growth arrest on the normal leg, by femoral shortening after skeletal growth maturity has taken place or by lengthening of the short leg have been fairly well divided among the orthopedic surgeons who have had experience in dealing with this problem.

The most formidable of the three procedures is actual lengthening of the shorter extremity; this should not be undertaken in any instance in which the bones that are to be lengthened are decidedly atrophic from paralytic disuse.

If the spine is completely flexible and without evidence of structural scoliosis, no great damage may result from delaying surgical procedures until skeletal maturity has been achieved.

A more accurate equalization of leg length can be obtained through the resection of a carefully measured segment of the femur. The healing of the femur following such resection may be prolonged over a period of six months or more, and this procedure certainly does represent a much more formidable operative and postoperative program than is required by epiphysial growth arrest.

For the patient described, an arrest of growth of the distal end of the femur would be a much more simple and safe operation. In all probability, an arrest at this age would bring about approximate equalization of the length of the leg, by the time this boy is fully grown.

Deformities resulting from growth arrest operations have not been significant. In an occasional patient the arrest becomes complete for one femoral condyle before it does for the other, resulting in some degree of knockknee or bowleg. If the operation is thorough, with a bone graft laid across the epiphysial line, as described by Phemister, a complete checking of longitudinal growth from the lower femoral epiphysis can be anticipated within a period of three to five months and no deformity will result. In an infrequent instance as a result of the growth arrest the leg that was originally short may be a little longer than the other leg when full skeletal maturity has been reached. In no instance that has been recorded has this difference been significant.

SCALENUS ANTICUS SYNDROME

To the Editor:—Give details on diagnosis of "scalenus anticus syndrome."

What per cent of disability is ordinarily allowed for a simple fracture of the clavicle?

What is the latest and most acceptable book giving interpretation and per cent of disabilities allowed for various types of injury?

M.D., New Jersey.

Answer.—Symptoms of the scalenus anticus syndrome are as follows: The patient usually complains of pain over the outer surface of the shoulder on the involved side. This pain may extend down the arm or radiate up the back of the neck with referral to the seventh cervical spinous process (vertebral prominens). At times the pain may be referred along the course of the ulnar or median nerves in the arm and forearm. The pain can be relieved if the patients turns his head to the affected side or raises his elbow. Frequently there is tenderness of the scalenus muscle at its attachment to the first rib. Decreased sensation to all forms of stimuli occur in the arm and forearm; atrophy and total loss of sensation are seldom seen. Treatment is either palliative or surgical. The former is used in mild cases as exercise of the involved shoulder region in order to strengthen the trapezius and other muscles which elevate the shoulder girdle. In most cases surgical treatment is required. This consists of sectioning the scalenus anticus muscle and also any fibers of the scalenus medius which seem to be tense. In some cases resection of a cervical rib may be necessary. This syndrome was originally described by Naffziger of San Francisco. For an excellent description refer to the original article (Naffziger, H. C.: The Scalenus Syndrome, *Surgery, Gynec. & Obst.* **64:**119, 1937).

Usually in a simple fracture of the clavicle without displacement or overriding of the fragments there is no percentage of permanent disability because there is no disability.

Since the Industrial Commissions in the various states of the union operate individually, there is no publication on percentages of total, temporary or permanent disability that can be purchased. Write to the Industrial Commission in your state. They can give you the information you need.

TUBERCULOSIS IN DIABETIC PERSONS

To the Editor:—What is the incidence of tuberculosis among diabetic persons as compared to that of tuberculosis in the general population. Can this information be broken down to reveal the percentage of cases observed in diabetic clinics versus those first seen in hospital wards (i. e., uncontrolled and complicated cases of diabetes mellitus) and those first observed in tuberculosis hospitals? Recent discussion in a diabetic clinic brought out the point that not a single case of tuberculosis had been seen during the time that chest surveying had been instituted at the clinic. My feeling is that controlled diabetes would not exhibit an increased incidence of tuberculosis, whereas it might be noted among persons with uncontrolled diabetes (hospitalized patients) or those already in tuberculosis hospitals.

Jean P. Papps, M.D., Forest Hills, N. Y.

Answer.—Prior to the advent of insulin necropsies revealed that one fourth to one third of persons dead from diabetes also had tuberculosis. However, since 1926 tuberculosis in an active stage has seldom been found at necropsy in more than 6 or 7 per cent of diabetic persons. H. F. Root in 1934 (*New England J. Med.* **210:**1, 78, 127 and 192, 1934) published extensive observations on the association of diabetes and tuberculosis. He found that active tuberculosis occurred in diabetic patients at necropsy between two and three times as frequently as among nondiabetic patients. Among 750 children in whom there developed diabetes before the age of 15 years the reinfection type of pulmonary tuberculosis was more than thirteen times as frequent as in Massachusetts school children. Among adolescent diabetic patients who contracted the disease between the ages of 15 and 20 years, pulmonary tuberculosis occurred sixteen times as frequently as in Massachusetts high school students. There was roentgenologic evidence which suggested active pulmonary tuberculosis in 2.8 per cent of 1,373 adults with diabetes.

A. L. Banyai and A. V. Cadden (The Rationale of the Therapeutic Administration of Massive Doses of Vitamin A in Tuberculous diabetics, *Dis. Chest* **10:**133, 1944) reported that 2.6 per cent of a large number of diabetic patients were found to have pulmonary tuberculosis. Wiener and Kavee (*Am. Rev. Tuberc.* **34:**179, 1936) reported that 23.9 per cent of 909 diabetic patients had tuberculosis. However, this high figure is probably due to the large proportion of the patients in Montefiore Hospital, New York, who have tuberculosis. Himsworth (Pulmonary Tuberculosis Complicating Diabetes Mellitus, *Quart. J. Med.* **7:**373, 1938) has collected data which show that since the introduction of insulin pulmonary tuberculosis develops in 2.7 per cent of those with diabetes.

There is good evidence that the increased incidence of tuberculosis in diabetic patients now is for the most part among those whose diabetes has been uncontrolled or inadequately treated. When the two diseases are associated the diabetes is discovered before the tuberculosis in 65 to 80 per cent of the patients. Tuberculosis appears more frequently among those with severe forms of diabetes than among those with mild forms. For example, among those who had diabetic coma, in 8 per cent tuberculosis developed within three years, which is fourteen times the incidence of pulmonary tuberculosis in the general population. J. Kavee (Pulmonary Tuberculosis and Diabetes Mellitus, *Bull. Am. Acad. Tuberc. Physicians* **4:**147, 1940) observed pulmonary tuberculosis both in mild and in severe cases of diabetes at the Montefiore Hospital. However, the proportion of patients with pulmonary tuberculosis who had the severe form of diabetes was much greater than usual among diabetic persons of similar age. It has been generally observed that diabetic patients with pulmonary tuberculosis nearly always require insulin. Likewise, pulmonary tuberculosis in the presence of diabetes usually requires collapse therapy.

Kavee reported that among 332 patients who entered Montefiore Hospital only 17 had well controlled tuberculous lesions. In 15 of these cases the tuberculous lesions had not progressed or reactivated over a considerable period of observation, some as long as ten years. Since old inactive pulmonary tuberculosis seldom becomes reactivated and since minimal pulmonary lesions without symptoms, cavitation or positive sputum often recede in persons with well controlled diabetes, there apparently is little likelihood that persons with well controlled diabetes who are free from tuberculosis are any more likely to have primary lesions and the subsequent reinfection type of disease develop than are persons in the general population. Therefore, your contention apparently is correct.

Nevertheless, every diabetic patient whose condition is not adequately controlled should be kept under close observation, as such persons are two or three times more likely than others to acquire clinical tuberculosis. Both reactors and nonreactors to tuberculin should be closely guarded against contact with contagious tuberculosis, as first infection and reinfection are dangerous to them.

There is no reason to suspect that persons with well controlled diabetes are less likely to contract tuberculosis than those in the general population. Therefore, even the best controlled patients should be carefully protected against first infection and reinfection types of tuberculosis. Should clinical disease appear and show evidence of continued activity, collapse therapy should be promptly instituted.

RADIOIODINE

To the Editor:—What are new trends or methods of treating cancer? A woman, aged 68, has a malignancy of the throat. She had had a complete series of high voltage roentgen therapy and had shown little or no improvement. The family have been reading about radioactive therapy and also the use of atomic therapy and would like to know the advisability of using that on the woman. I know nothing about such treatment and would like advice about the matter.

M.D., Illinois.

ANSWER.—What is meant by "malignancy of the throat?" Without better information part of the question is unanswerable. The term "atomic therapy" is not familiar. "Radioactive therapy" probably means use of one of the radioactive isotopes. If by "malignancy of the throat" the correspondent by chance might mean cancer of the thyroid the answer would be that radioactive iodine has a limited value in certain types of the disease, its value being dependent on the results of preliminary tracer studies for iodine pick-up by the tumor. Nothing is known of any isotope of potential value in any other type of cancer which is primary in the area described and which is proved to be radioresistant to the roentgen ray. Even if the tumor is a lymphosarcoma, if it is resistant to roentgen therapy there would be no reason to hope that it would respond to a radioactive isotope.

ACROMEGALY

To the Editor:—A man aged 30 presents some of the clinical features of acromegaly (increase in the length of bones of the hands) and hypogonadism (impotence, small penis and testicles, obesity of female type, scanty beard growth).

Roentgen examination of the skull revealed an enlargement of the pituitary fossa (25 mm. by 11 mm.) with destruction of the dorsum sellae and the anterior clinoid processes. His basal metabolic rate was minus 15 per cent; the cholesterol content of the blood was 400 mg. per hundred cubic centimeters. He has no glycosuria. The blood sugar curve was rather flat. Eye examination did not reveal abnormality of the fields of vision or evidence of choking of disks.

The patient's only complaint is impotence. He claims to have had normal sexual functions some eight to nine years ago. There occurred a sudden increase in weight four years ago during a particularly strenuous period (during the Italian Campaign).

What substitutive treatment is indicated? Is irradiation of the pituitary imperative or could it wait until signs of further extension of the tumor develop?

Would chorionic gonadotropin be useful, and to what extent could it cure the patient's impotence? What is the prognosis?

M.D., Newfoundland.

ANSWER.—In acromegaly there is a disturbance of many of the glands of internal secretion, and of course the pituitary gland is one which has to do with sexual desire and ability. I believe that administration of the hormones is indicated. The substance used may be "Antuitrin S" (chorionic gonadotropin) or alcohol extracts of anterior pituitary, testicles and the adrenals, with which there has been some success and which may be administered every other day until a series of twelve injections has been given.

Irradiation of the pituitary is not absolutely essential unless signs of further extension of the tumor develop.

The prognosis in such a case is poor, and the course of injections may have to be repeated on numerous occasions.

DERMATITIS PATCH TESTING

To the Editor:—A patient, aged 60, a railroad agent, has a severe dermatitis on his legs, hands, arms and face. It has occurred at intervals during the last two years. I believe it is due to a rubber raincoat, similar to the type used by the Army. What specific substance in the raincoat would be likely to be responsible for the dermatitis? Might it be due to tetramethyl thiuram disulfide?

Delmer E. Johnson, M.D., Alamosa, Colo.

ANSWER.—To incriminate the raincoat a patch test with the inside or the lining of the raincoat should be positive. Even this would not be absolute proof, because it is most unusual for a contact dermatitis to develop on parts which are not in contact with the article of wearing apparel. Raincoats are not usually worn in contact with the skin, and it is hardly conceivable that a chemical in the raincoat or on its external surface would leach out in sufficient quantity to penetrate through the clothing and reach the skin.

Once the raincoat has been established as the cause of the dermatitis, the manufacturers of it should be requested to give the composition of the material from which it was made and the chemicals which it contains.

The Army had raincoats made of vinyl resin films ("vinylite," "koroseal"), of fabrics coated with these films and of rubberized fabrics.

It has been found that plasticizers and stabilizers are the most common sensitizers in the vinyl resin films. In rubber materials the usual sensitizers are the accelerators, the antioxidants and the chemicals formed on the surface of the rubber by the so-called acid or vapor cure, in which sulphur monochloride is the curing agent. Tetramethyl thiuram disulfide ("tuads") is only one of the many rubber accelerators which has been reported as causing sensitization dermatitis.

When the chemicals in the raincoat have been ascertained, patch tests of the patient with each of them, using the proper technic, may reveal the chemical to which the patient is sensitive.

HOOKWORM INFESTATION

To the Editor:—Are there reported cases of bronchial asthma caused by hookworm infestation? What is the treatment other than elimination of the parasite from the alimentary canal?

Herbert A. McClure, M.D., Lake City, Fla.

ANSWER.—Infestation with parasitic worms produces a hypersensitivity that is evidenced on skin test by an immediate wheal from intradermal injection of an extract and the finding of transferable antibodies (reagins). These facts provide the basis for the possibility that allergic manifestations such as asthma can be produced by hookworm infestation. Reports of authenticated cases were not found in the literature. Elimination of the hookworm infestation is the logical procedure in such a suspected case.

PERSONALITY AND CHRONIC ILLNESS

JURGEN RUESCH, M.D.
and
KARL M. BOWMAN, M.D.
San Francisco

The way a person lives determines in part the disease he will contract. This concept, which for centuries was known to be valid for occupational and infectious diseases, has been extended in recent years to include not only exposure to specific noxious agents but repeated and chronic exposure to subtle and nonspecific trauma as well. While epidemiology and public health and preventive medicine have been particularly interested in the habits of people with occupational and infectious diseases, psychosomatic medicine has concentrated on similar aspects in persons with chronic disease. However, it was found that study of habits alone was not sufficient, but that the whole life situation of the patient had to be encompassed. Living means interaction with the environment. Conflict arises when the environment actually interferes with a person's wishes or when he anticipates that interference will or would occur. The resulting stress and strain, if persisting over a long period, creates or contributes toward physical and mental pathologic states. In medicine, therefore, personality studies serve the physician's purpose of inquiring into behavior patterns and conflicts in order to formulate preventive and therapeutic measures.

THE MAGNITUDE OF THE PROBLEM

In the United States about 25,000,000 people suffer from disabling or nondisabling chronic disease.[1] Furthermore, the age of the patient, as well as the mortality and morbidity for, and the duration of disability from, chronic conditions, are steadily increasing. Advice counseling and psychotherapy may prevent illness in patients who are prone to accidents, who tend toward chronic alcoholism; who are promiscuous and contract venereal disease and who have gastrointestinal and vascular conditions. In cases of invalidism from arthritis, myopathy, neurologic disease, tuberculosis, blindness, deafness, amputation of the extremities and other disfigurations, psychologic adjustment to the disability is frequently the only therapy. Whereas in former centuries disease and accident killed a great many people, thus making longevity rare, the triumphs of medicine have extended considerably the life expectancy in modern times. However, every single advance in medicine upsets the existing social structure in a population; this unbalance, in turn, creates new medical problems; therefore, one has to recognize that the sociopsychologic problems created by scientific advances are also a responsibility of medicine. At the moment, the burden is carried by public health services, preventive medicine, population studies and insurance medicine, all of which emphasize the mass aspects of this problem, while personality studies approach the same question from an individual standpoint. But soon the medical profession at large will have to share in the management of social and psychologic problems in medicine if an adequate job shall be done.

The personality of the patient already becomes a frequent topic and concern of medicine; this tendency is clearly borne out by the ever increasing number of publications concerned with psychologic problems in relation to illness. Since time prohibits a detailed survey of the literature, reference will be made to three sources only. The most comprehensive review of problems of adjustment to physical handicaps and illness was made by Barker, Wright and Gonick [3]; Dunbar's [4] abstracts of the literature on psychosomatic problems appeared in a new edition, while Saul [5] summarized facts and concepts prevailing in this field. Recently a number of organizations have sponsored personality studies in relation to illness. Under the auspices of the Office of Scientific Research and Development, the division of psychiatry of the University of California Medical School investigated psychologic aspects of delayed recovery from accidents and illness; syndromes following head trauma,[6] invalidism following chronic disease in general,[7] duodenal ulcer [8] and disability following thyroidectomy [9] were the topics of this four year study. General principles, approach, methods and results of these personality studies will be discussed with the help of this material.

SPECIFICITY OF PSYCHOPHYSICAL CORRELATIONS

In psychosomatic medicine there exist two slightly different approaches. Some authors hold that each physical condition should ultimately be related to specific psychologic conflicts and social constellations. Though there exists enough evidence to point out that patients with duodenal ulcer, for example, resemble each other so far as psychologic and social features are concerned, one may, on the other hand, find similar aspects in patients with chronic alcoholism. Therefore, a second opinion holds that there are no such specific correlations of conflict, personality structure and physical manifestations, but that stress and strain can be associated with a multitude of physical reactions. The choice of system and organs affected is said to be determined by other than psychologic reasons, but once the pathologic or pathophysiologic condition is established, tension and frustration perpetuate and aggravate existing conditions.

In considering the evidence in favor of either of these arguments, one must admit that both opinions can be supported by facts. Psychosomatic syndromes, apparently, have to be divided into subgroups in order to be fully appreciated.

The most specific relation between conflict and symptom is found in hysterical patients, in whom paralysis of one or more of the extremities, blindness and other symptoms have a specific meaning. They are used by the patient to solve temporarily an otherwise unbearable conflict.

In a second type the physical pathologic condition is incidental and the result of conscious or unconscious attitudes or desires. As examples may be mentioned persons who overeat, who permanently clear their throat, who scratch their skin, suck their thumb, bite their finger nails, drink liquor, consume barbiturates or expose themselves to accidents. In these patients there exist frustrations which are managed by some kind of activity, which in turn leads to deformity, illness or accident.

A third, and slightly different, relation between frustration and disease is found in a number of vascular, gastrointestinal and pain syndromes. One has to remember that frustration is psychologically expressed in anger and physically in terms of tension. Outside interference with a person's goal-directed behavior produces anger and tension and prepares the organism for fight or flight. The pulse rate and blood pressure go up; muscular tension ensues, and some biochemical changes take place. After release of energy in terms of action, the organism returns to its normal resting condition. However, in modern civilization the primitive reactions of flight or fight cannot be used without previously learning complicated procedures and modifications of these primitive reactions, and many persons are unable to acquire these socially acceptable forms of behavior. While the normal person channelizes aggression in work, play and sex, maladjusted and immature persons are unable to release pent-up energy. Anger and tension, therefore, persist over prolonged periods because no discharge of energy occurs. This condition of suspension seems to influence vascular, muscular, secretory and endocrine reactions.

The fourth, and most nonspecific, type of mind-body relation occurs when incidentally acquired illness coincides in time with some psychologic experience which has nothing to do with the disease.[7] It is old knowledge that if a person is sick and receives unfavorable news he may have a severe relapse or prolongation of his condition. In such a case frustration brought about by disease is combined with frustration brought about by the psychologic conflict, and the two together may be more than the patient can bear. In addition, the two events get tied up together and subsequent behavior follows the laws of conditioning and deconditioning; as long as the psychologic conflict lasts, the physical disability is continued, and vice versa.

The fifth, and last type that must be mentioned is the direct result of medical or surgical treatment. For example, therapy can lead to drug addiction, barbiturate or bromide intoxication, multiple operations, roentgen ray burns and similar conditions, while insecurity of the physician may lead to superfluous and damaging perpetual diagnostic examination. If the person happens to be neurotically inclined, physical treatment for psychogenic symptoms inculcates in him the idea that his disease is physical, that there is nothing he can do to recover, and he then becomes an invalid.

VARIABLES USED IN PERSONALITY STUDIES

Personality can be described in various terms. Fundamentally, one can distinguish between static and dynamic features. The static variables describe the personality in terms of recurring or consistently present features; as examples may be mentioned intelligence, personality traits and attitudes. In contrast, the dynamic variables attempt to describe the processes themselves, which occur either within the person or in his contact with the outside world. It is obvious that these dynamic aspects are technically more difficult to approach but that, at the same time, they contain more valuable information. It would be a fair statement that up to recent times the static variables were the domain of the psychologist, the individual dynamic variables the domain of the psychiatrist and the social dynamic features the domain of the sociologist and the cultural anthropologist. In our present studies we have attempted to have all three types of variables represented because combined they yield a rather complete description of the personality.

STATISTICAL RESULTS IN PATIENTS WITH CHRONIC DISEASE AND PSYCHOLOGIC INVALIDISM

Overt clashes with law-enforcing agencies are rare. Persons with chronic disease are on the whole law-abiding citizens; instead, maladjustment is expressed in terms of disease and sexual and marital difficulties.[7] For all groups, the divorce rate for the women is considerably higher than that for the normal population. Their health record varies. Thyroidectomized and posttraumatic patients have a higher number of hospitalizations than patients with duodenal ulcer, for example.

Intelligence.—All patients with chronic syndromes studied had an above average intelligence, in spite of an average education. It follows that the more intelligent persons tend to have difficulties with recovery and adjustment to disability.

Personality Profiles.—With the use of objective personality tests, such as the Minnesota Multiphasic Personality Inventory, or of projective technics, like the Rorschach test, the Thematic Apperception Test [10b] and play technics,[10a] the fact is clearly revealed that the majority of patients with chronic disease have a highly abnormal score, and one very much like persons who suffer from clearcut psychoneuroses without any physi-

cal symptoms. Results of these tests prove objectively that measurable psychologic aberrations exist in these persons; the degree of abnormality is about equally great in patients with chronic invalidism from a variety of causes such as chronic duodenal ulcer, chronic alcoholism and protracted syndromes following head injury, and in patients with persisting nervous symptoms following thyroidectomy.

CHILDHOOD HISTORY

Considering first the objective aberrations shown by the childhood history, one finds in almost all groups a high incidence of broken homes.[11] This is particularly true of the thyroidectomized patients. In a mixed group of patients with chronic disease and patients with duodenal ulcer, an unusual incidence of youngest and younger children was found, which significantly exceeded that of oldest and older children. In contrast, the thyroid patients tended to be the older or the oldest children. These facts are of importance, for it is known that the oldest and the youngest children are more exposed than those in the middle of the family; youngest and younger children usually receive more care from adults and older siblings than do children who are in the middle of a large series. Furthermore, the youngest children are usually isolated in terms of age relationship with other siblings, a situation which, in turn, promotes fantasy development and dreaming rather than the reality experience. For example, the adaptive behavior of a child who is the fourth in a series of seven is greater because social technics are learned for the handling of parents, older siblings and younger siblings. In contrast, the youngest children learn only the technics which are related to the handling of older siblings and parents, which methods are known to comprise submission, rivalry, avoidance and adaptation, rather than overt dominance. People who exert overt dominance do not seem to have prolonged recovery, whereas, in contrast, people who always have to adapt to others, who depend on being told what to do, are inclined to be sick for prolonged periods.

An attempt was made to reconstruct the relationship with the parents. For this purpose three factors were considered essential.[12] The major source of authority reenforcing the behavior of the child by reward or punishment was considered the outstanding feature. The second essential factor was labeled "ideal model." It constitutes that source from which the child takes over cues, imitates behavior and copies manners and gestures. If the relationship to the ideal model is a sound one, the child will identify thoroughly with that person; if, however, the relationship is a poor one, the child will identify only partially and is likely to take over external mannerisms rather than internal values. The third factor considered was the source of affection. In the normal boy and girl both parents are sources of authority, ideals and affection, whereby in the boy the authority and ideals derive more from the father, and in the girl, more from the mother.

In reconstructing these childhood events, it was discovered that among the patients with ulcer, for example, there was not a single person, and of thyroidectomized women only one-third, with a normal pattern. The patients with other forms of chronic disease were distributed into patterns which were characterized by an overbearing, dominant mother and a remote father, or vice versa, by a punitive, overbearing father and a weak and ineffectual mother. The essence of these findings was that concentration of authority, ideals and source of affection in one and the same person provokes the child to develop one-sided technics, rendering him oblivious to the fact that later in life other situations and other people will require different technics. In contrast, in families in which both parents fulfil their function the technics are more diversified, and if punishment occurs it does not threaten the relationship to both parents, but usually only that to one parent at the time. In case of the dominant mother punishment actually undermines the whole existence of the child. With the help of these childhood patterns it was easy to trace the development of the adult character abnormalities described in the next paragraph.

CHARACTER CONFLICTS

In rating the outstanding character conflicts of our patients, we found that in all men the problem of dependence versus independence was most prominent.[11] By "dependence" is meant the need of a person to monopolize, or permanently to ascertain, the flow of affection of one or more human beings. In reality, this is done either by submitting, subordinating and attempting to please, taking care never to express any antagonism or anger, or, in contrast, by striving for unusual achievements and assumption of responsibilities. The difference between normal and dependent patients is seen in the fact that dependent persons break down either when the source of dependence is withdrawn, as in separation, or when achievement and compensatory striving are made impossible. Such is particularly the case with patients who have duodenal ulcer.

In women the problem of choice between self love and love of other persons was a primary conflict. It was most clearly expressed in hysterical personalities; being unable to remain attached to others, these women maintained highly unstable relations, which fact was expressed in their high divorce rate. Their affinity to others was characterized not by empathy and the like but, instead, by using these other persons to feed their vanity and to applaud their own tendency to show off. As long as change enabled these women to assert their desirability things went fairly well, but as soon as marriage and permanency were required these women lost their mechanism of self assertion and broke down.

It is our impression that in medicine the dependent man and the hysterical woman represent the major cause of invalidism. We found this to be true for men with duodenal ulcer, head injuries, goiter and certain forms of hypertension. In women the hysterical characters appear in cases of thyroid disease, hysterical pain syndromes, polysurgery, post-traumatic syndromes and other groups; to put it in other words, in dependent men and hysterical women the susceptibility to disease and accident is greater, the chance for recovery poorer and the time of convalescence longer.

GROUP MEMBERSHIP

In studying formal and informal associations to which these patients belong, one obtains a great deal of knowledge concerning the patients themselves. This approach conceives the individual not so much as the product of a unique combination of features, but more the result of group influences to which he has been subjected, directly, in his contacts with outsiders and, indirectly, through his parents and their contacts. To use a comparison, if one wants to gain insight into the life of ants or bees, one has to study the social organization in which they live; the same is true of patients.

---

[11] Ruesch and others, footnotes 7, 8 and 9.

[12] Ruesch and others, footnotes 8 and 9.

Considering first the social class membership, one must turn to studies made by leading sociologists and anthropologists.[13] It has been conclusively shown that American society is not distributed evenly along a continuum from poor to wealthy, from disreputable to reputable, from unsuccessful to successful, but that the population clusters in groups, which are called social classes. This term is just another way of saying that the industrial workers, for example, have different associations, beliefs and attitudes than middle class people who live in country club heights; these, in turn, have different attitudes than the millionaires whose wealth has been passed on from generation to generation. The social classes are of importance with relation to disease because they induce the people to live according to certain standards and norms. Persons of the lower class, for example, are more exposed to industrial hazards than the middle class white collar worker, but in turn, psychosomatic conditions and chronic illnesses seem to concentrate around the middle class.[7] Whether this is a true picture of the incidence of illness, or whether it merely reflects the fact that the middle class person goes to the physician and the hospital and is better fitted to survive illness and accident because of his better environment, cannot be decided at present; but it is known that people with chronic disease and psychologic invalidism have many characteristics of the middle class. They are law abiding, and, up to the time of the disease, self supporting; they are conformists, and their repressive tendencies are great; their field of awareness is rather limited, and they have difficulty in expressing anger and in managing tension.

In America there exists a premium for people who make good. Working themselves up and achieving fame and prestige is one of the recognized ways of living. This public ideology, in turn, imposes unusual stress and strain on the individual. People feel the necessity to improve their condition, rather than to enjoy their existence. The striving for betterment, income, position, power and property requires a permanent adaptation of the individual to new groups. He has to undergo a remarkable change in his system of values, in his technics of mastery and in the habits and customs acquired in childhood if he changes from one social class to another. In such a change the "know how" is lost; the person becomes isolated; and a social, mental or physical pathologic state is the result. We have been able to show that among patients with chronic disease in general, with duodenal ulcers and with thyroid disorders there is an unusual number of social climbers and strainers, that is, persons who want to improve their social status. This is in contrast, for example, with the findings for chronic alcoholism, in which condition the patients have usually fallen socially. In patients with ulcer and thyroid conditions in particular, there was an unusual incidence of foreign-born and native-born persons of foreign parentage. This fact would indicate that culture change and the resulting conflict of values were a source of stress and strain in these patients.

CULTURE CHANGE AND DISEASE

In the course of these studies, it became apparent that culture change plays a major role in chronic disease.[14] Regardless of whether the change involves moving from east to west, from country to city, from civilian to military life or from Navy environment to home, from one social class to another or from foreign born to American, the principles involved remain the same. We have estimated that approximately one half the American population at any one time is in the process of culture change. This involves readaptation and relearning of ways of living, attitudes, beliefs and system of values. While undergoing this change, there exists a particularly critical phase in which the individual is well underway toward giving up the old system of values and his membership in the old groups but has not yet mastered the new values of, and is not yet rooted in, the new groups. Isolation is the result; the need for social recognition cannot be gratified, and frequently refuge in chronic invalidism seems to be the only possible solution. Illness in itself, however, may serve a double purpose; it establishes the patient in a hospital and among sick people, while at the same time it justifies isolation and makes the social situation tolerable

ATTITUDES TOWARD PHYSICIANS

Interviews and inventories were used to study the attitude of various groups of patients.[12] The results indicated that the physician-patient relationship was largely governed by features which had little, if any, relation to medicine. Attitudes toward parents, substitution of physician for parent, desire to receive attention and affection and the striving to climb socially were frequently more important than the doctor's knowledge. For example, the most neurotic patients, in terms of personality profiles, described the doctor as having nurturant and supportive features, while the most normal patients emphasized the desirability of a good character in the physician. Social climbers and strainers tended to project their own problems onto the physician and assigned the doctor authoritarian qualities. A clearcut relationship between childhood patterns and the attitude toward the doctor was thus established. Patients with an idealized and beloved mother tended to idealize the physician, while patients with an authoritarian mother expressed a desire for medical authority. The medical attitude scales also revealed that lower middle class people were readier to accept gullibilities in terms of popular sayings, superstitions and advertisements of quacks than were people of the upper middle class or the lower class. The latter feature indicates that a certain degree of naïveté and conformity promotes psychologic invalid reactions, while skepticism and nonconformance are deterrent to delayed recovery.

PROGNOSIS

With the help of the Minnesota Multiphasic Personality Inventory, it was possible to predict the speed of recovery.[15] Patients with delayed recovery from a variety of diseases had more abnormal profiles than those with normal recovery. With the same method, it was possible to show that patients with relatively normal profiles were better subjects for psychotherapy and improved under relatively shorter treatment than those with more abnormal profiles.

SUMMARY

Though differences exist among the various groups of chronic illnesses studied, the features which the patients have in common by far outweigh their differences. On the whole, one may state that the most essential features of these patients were found in their lack of adaptive behavior and in unsatisfactory technics in meeting social changes. Whenever a change in the relationship between these patients and their environment produced a stress situation, the patient tended to break down. These changes were related either to daily events, such as death, birth or marriage, or to more fundamental issues, such as culture change. Here, relearning of external symbols, habits and attitudes, as well as reorientation of internalized values, was more than the patient could bear. Adaptive behavior and psychologic awareness, in turn, were inversely related to the need for conformance of these patients. Conformance in the American society is most pronounced in the lower middle class and diminishes toward both ends of the distribution. The lower middle class, with its tendency toward compliance, is more gullible and tends to accept more readily everything at its face value, which features obviously handicap adaptive behavior. This particular constellation of factors seems to be responsible for the concentration of psychologic invalid reactions in the middle class. However, in all social classes one meets abnormalities of character brought about by devious childhood situations. Though the child was prepared to manage the immediate family environment, he or she failed when thrown on his own. Invalidism, then, is the temporary solution to failure in socialization and successful experimentation with reality. The dependent male and the hysterical female are the prototypes of personalities which tend toward delayed recovery, invite abuses in medicine and surgery and, generally speaking, make the life of the physician unnecessarily difficult. Early recognition and psychotherapeutic treatment tend to prevent disagreeable complications.

ABSTRACT OF DISCUSSION

Dr. O. Spurgeon English, Philadelphia: As the chairman has shown, all are only relatively well conditioned to responsibility, so that every one continues to have some specific dependency needs. Therefore, in every acute illness and in every surgical operation, no matter how skilfully or well done, the experience tends to combine with and to enhance these dependency needs and to make one a victim of what may be called acute invalidism, with a predisposition to chronic invalidism. It seems, however, that we physicians are becoming more aware of these possibilities. In every hospital, and in every practice, we must try to do more about them with the patient if we are to reduce the amount of invalidism which follows nearly every operation or illness. I might say a word about what is called the countertransference in attempting this maneuver. After a person has had an illness, or an operation, one may be reluctant, no matter how carefully it is phrased, to ask the patient what amounts to whether he is capitalizing on his illness or his operation. That is a difficult matter to take up with the patient, but I believe we have a duty to society to do so and an obligation to the patient to do something for his own good, and thereby to prevent those days, and sometimes weeks and months, which are occupied with convalescence.

Dr. Karl M. Bowman, San Francisco: The new idea of getting patients up and out of bed a few days after an operation is a method of preventing chronic invalidism, and probably has a psychologic more than a physiologic basis, although it has both. A patient who is made to lie in bed several weeks after an operation is conditioned to inactivity and is more likely to become a chronic invalid. If, however, a patient is persuaded to get up two, three or four days after an operation and is encouraged to resume as many activities as possible, it woll help prevent the delayed recovery response which is such a common precursor of the chronic invalid reaction.

LOCAL TREATMENT OF CARRIERS OF VIRULENT DIPHTHERIA WITH PENICILLIN

A. J. LEVY, M.D., Ph.D.
Dixon, Ill.

From the Dixon State Hospital, Warren G. Murray, M.D., Superintendent and the Department of Public Welfare, Springfield, Ill.

Rosenau[1] stated that under normal conditions 1 or 2 per cent of any population harbor virulent diphtheria. When an acute case of diphtheria occurs in a locality, the incidence is considerably increased (to about 14 per cent in institutions), and according to Schick[2] it varies from .3 to 83 per cent. Zingher.[3] found that the carrier rate in a community is even higher than that suggested by Rosenau, varying between 4 and 5 per cent.

Institutions, orphanages, camps, prisons, schools and state hospitals, or places which house an aggregation of many under one roof, serve as fertile soil for the spread of diphtheria. Therefore constant vigilance must be maintained to protect school children, inmates, patients and employees against this disease. Diphtheria carriers in a well protected community may be considered harmless. However they still are a menace to that portion of the population which lacks immunity, for in spite of all precautions sporadic cases do occur.

Many methods have been suggested for the treatment of diphtheria carriers, such as the use of antiseptics in swabbing, spraying, gargling and inhaling, the injection of serums, toxins, antitoxins and vaccines or the supplanting of the virulent Corynebacterium diphtheriae by cultures of staphylococci or yeast. However, none of these methods has been satisfactorily effective. Since at times C. diphtheriae are imbedded in the tonsillar crypts, tonsillectomy is often performed, but with only partial success. None of the known sulfonamide compounds is effective. Administration of penicillin parenterally is of little value. However according to the latest reports there are encouraging results with the use of penicillin locally in the form of lozenges and sprays. Since this form of administration for diphtheria carriers is still in the experimental stage, it may be of some value to bear in mind that although the reported cases are few in number the successful results may serve to further the study of the effect of penicillin administered locally in the treatment of diphtheria carriers.

During the latter part of February 1946 the Dixon State Hospital experienced a minor outbreak of diphtheria among patients and employees. In spite of the fact that all patients had been immunized with three doses of fluid toxoid, 4 of them contracted diphtheria. One of these, L. S., had received three injections of diphtheria toxoid at a monthly interval after admission to the institution. At the time of her illness only four months had elapsed since she had been immunized. Therefore she was not given a Schick test. The other 3 patients had been immunized four or five years before. When they were given a Schick test six months after immunization the reaction was negative. Because the institution was understaffed during the war, Schick tests had not been performed on the patients routinely since 1941 and 1942, so that the status of immunity to diphtheria could not be determined.

On February 26 L. S., from the tuberculosis ward of the institution, experienced a sore throat, inability to swallow and swelling of the pharynx and the anterior cervical glands. This swelling was more pronounced on the right side, and the patient had a temperature of 101 F. Since she was an uncooperative patient of low grade mentality and since there was enormous cervical swelling it was impossible to examine her throat thoroughly. A diagnosis of abscess of the throat was considered, and swabs were taken and sent to the Illinois State Department of Health, Division of Laboratories. Pending the return of the laboratory report, the patient was given 20,000 units of penicillin intramuscularly every three hours, but she did not respond well to this treatment. On March 1, three days later, when the laboratory report indicated the presence of diphtheria, the use of penicillin was discontinued. She was treated with antitoxin and responded well.

During the outbreak, 3 additional inmates and 2 attendants whose laboratory reports showed that they had diphtheria were isolated and treated with antitoxin.

On March 11, in order to attempt to locate the source of diphtheria, examination was made of the nose and throat of 125 patients and attendants of the tuberculosis ward for females as well as of all those in the general hospital where L. S. had originally been hospitalized. On March 15 a laboratory report showed that 15 patients, or 11.8 per cent, were diphtheria carriers. All were isolated, but they were not immediately treated. On March 27 the virulence tests indicated that 13 patients were carriers of avirulent organisms. They were released, except for 2 patients who were carriers of virulent C. diphtheriae, and were retained in the Isolation Hospital for treatment. They were given penicillin lozenges of 1,000 units each, administered every two hours for six days. Each lozenge lasted for about two hours when held under the tongue. This frequent administration was needed to retain a continuous flow of the penicillin on the mucous membrane.

A third patient, M. B., was found to be a carrier of virulent C. diphtheriae and was used as a control.

The effect of penicillin on carriers of virulent diphtheria was tested one day after the treatment was terminated and also a week later. On April 15 and at subsequent twenty-four hour intervals nose and throat cultures were taken on all 3 patients. The culture of material from the 2 treated patients was negative, while that from the control patient was positive. On April 22 cultures were taken again. The laboratory report showed that the control patient was still a carrier of virulent diphtheria, both the throat and the nose being involved. Cultures of material from the 2 treated patients were still negative, and they were released from the Isolation Hospital.

At the beginning of June a fourth patient, L. T., was admitted to the Isolation Hospital as a carrier of virulent diphtheria. This patient and our previous control patient, M. B. were treated. Since the latter was a carrier of nasal and pharyngeal diphtheria, she was treated with 2 cc. of penicillin solution containing 10,000 units per cubic centimeter, administered by spraying with an atomizer every two hours for six days. Since the new patient, L. T., was a carrier of pharyngeal diphtheria she was treated with penicillin lozenges every two hours for six days. Here again the effectiveness of the drug was tested as before.

On Sept. 29, 1946, about six months later, nose and throat cultures were taken on all 4 carriers treated with penicillin lozenges and spray. On April 4, 1947, cultures of material from the nose and throat were again made, and they were negative.

COMMENT

As a result of this survey it was found that the majority of patients, 13 of 15, were carriers of avirulent diphtheria and only 2 were carriers of virulent C. diphtheriae. Unlike the work of Berman and Spitz,[4] Skinner[5] and Kocher and Siemsen,[6] this study was limited to patients who were carriers of virulent C. diphtheriae. The administration was not by the usual intramuscular route but locally by means of lozenges placed under the tongue or by spray. This was found to be more effective for diphtheria carriers because it seems that the lines of attack were directed to the affected areas, namely, the pharyngeal and nasal mucous membranes. It is believed that for acute cases as well as for the carrier state the parenteral route in the administration of penicillin was of little value. In the acute cases the object is to neutralize the toxin liberated from the body of the C. diphtheriae, which grows on mucous membranes of the nose and throat. The antitoxin then is the best weapon for combating diphtheria. Penicillin is considered a poor detoxifying agent.

In the carrier state C. diphtheriae seldom penetrate the underlying tissue of the mucous membrane as do hemolytic streptococci, but C. diphtheriae remain on the surface of the nose and throat, not affected by penicillin administered parenterally. Furthermore, the carrier has a high degree of immunity because of a high level of antitoxin in the blood. Therefore the carrier state may be compared to a symbiotic state in which the parasite and the host live peacefully together. In order to obtain a direct effect on the habitat of C. diphtheriae and affect their power of multiplication, penicillin must be given locally and more frequently.

Fleming,[7] Ercoli,[8] Abraham and others[9] and Chain and his colleagues[10] demonstrated that the C. diphtheriae is susceptible to penicillin in vitro. It is therefore necessary to bring the drug in direct contact with the organism for better results. Chain and his group demonstrated for the first time that penicillin could be used as a chemotherapeutic agent for diphtheria. Skinner,[5] Berman and Spitz,[4] Karelitz and others,[11] Bagnall and Bain[12] and Thrift[13] used intramuscular injections of penicillin in acute cases of diphtheria as well as in the treatment of carriers in the army and navy, but the treatment had little success. Thrift and Karelitz used penicillin locally in the form of sprays and nose drops every two hours, but the solution of 1,000 units of penicillin per cubic centimeter was not adequate. It is preferable to use 10,000 units of penicillin per cubic centimeter. Kocher and Siemsen[6] used

the drug both intramuscularly and in the form of lozenges and sprays. Of 31 carriers treated, the condition cleared up promptly in 74 per cent. Cultures were consistently negative. Unfortunately they did not distinguish between carriers of virulent diphtheria and carriers of the avirulent type.

When penicillin was used locally in the form of lozenges and spray, it was found in this limited study to be successful in the treatment of carriers of virulent diphtheria within one week, and the patients remained free from diphtheria even a year after the study was made.

SUMMARY

1. Penicillin is a powerful drug even against diphtheria when it is applied locally, repeatedly and in adequate concentration.

2. Four carriers of virulent diphtheria were successfully treated, 3 with penicillin lozenges and 1 with penicillin spray,

MEDICAL GROUP PRACTICE IN THE UNITED STATES

IV. Organization and Administrative Practices

MARCUS S. GOLDSTEIN, Ph.D.
Public Health Administrator, U. S. Public Health Service
Washington, D. C.

From the Division of Public Health Methods, U. S. Public Health Service.

The present article on medical groups, fourth in a series which will attempt to examine the various facets of group practice in the United States,[1] considers forms of organization and administrative practices in a number of medical groups throughout the country. A discussion of this phase of group practice (ownership of physical assets, distribution of administrative functions, mode of distribution of income in the groups and the like, should be of direct and practical concern to those who contemplate forming a medical group as well as to the groups already established and desirous of profiting from the experience of other groups. Also, an appraisal of current trends in group organization and administration would seem a matter of importance in the whole picture of medical economics in general. It is for these reasons that a cross section of conditions in existing groups is here presented.

PREVIOUS STUDIES

Rorem's study of 55 private group clinics in 1930[2] contains much pertinent matter on organization and administration at that time, the data being obtained by a mailed questionnaire to the groups involved. In the two reports on group practice by the Bureau of Medical Economics of the American Medical Association, first in 1933[3] and later in 1940,[4] data on organization and administration in medical groups were presented and discussed; these data were based on the response to questionnaires sent to secretaries of county medical societies in the earlier work, and to all listed medical groups in the later paper. A comprehensive treatment of the subject by Clark and Clark[5] appeared in 1941, on the basis of the published literature and their own studies of fifteen medical organizations. Data on types of organization of groups for medical practice, ascertained by questionnaires to medical groups throughout the country, were contained in a recent report by Hunt and Goldstein.[1c]

The foregoing are the larger studies in which the subject has received more or less quantitative attention. For other items in which organization and administration in medical groups may have received some attention, reference may be made to the literature on medical groups listed by Hunt[1a] and recent articles in the journal *Medical Economics.*[6]

PRESENT MATERIAL

One hundred and two medical groups are represented in the present sample, although not with regard to every item discussed. No sampling plan was employed in locating the groups. A member of the survey staff visited most of the known groups within a feasible distance of the main routes of his travel in twenty-one states. The sample is 28 per cent of all the known medical groups in the country as of mid 1946[1c] and varies from the latter in (1) a higher proportion of groups from the West South Central region and a lower representation of the Mountain and Pacific states, and (2) a greater proportion of large groups (36 per cent as compared with 20 per cent). As regards form of group organization (for practice of medicine), the present sample is virtually identical in relative representation of the several types noted in table 1.

The material is distinctive in that it is based on personal interviews rather than mailed questionnaires. Eighteen of the groups were studied intensively, a representative of the U. S. Public Health Service remaining about three weeks at each place studied; the other groups were visited briefly by a medical officer of the Service, as has been noted.[7] Naturally more information could be obtained at the former, and these will be dealt with in greater detail. It may be noted that the data refer to groups in practice during 1946-1947, and thus information on organization and administration is brought virtually up to date.

A word should perhaps be said about application of the definition of a medical group to the groups considered in the present report. The concept of a medical group has been discussed elsewhere[1a] the definition adopted in this study may be summarized as a formal association of 3 or more physicians providing services in more than one medical field or specialty, with income from medical practice pooled and redistributed to the members according to some prearranged plan. As is usual in social phenomena, observed conditions seldom fit a given definition precisely in every instance, the present series of medical groups ranging all the way from what might be considered ideal conformity with the definition to borderline conformity or even, strictly speaking, nonconformity so far as pooling and redistribution of income are involved. The latter types of groups are few in number and have been included because of "group" characteristics in other respects.

The materials on which the present study was based were collected by Miss Ruth Wadman and Dr. John R. Hague, largely under the direction of Dr. G. Halsey Hunt. Dr. Antonio Ciocco made most helpful criticisms and suggestions.

[7] Generous cooperation was afforded by these medical groups, especially the ones in which the intensive studies were conducted.

FORM OF ORGANIZATION

Table 1 gives the number of groups utilizing the specified forms of group organization for ownership of physical assets and the practice of medicine, respectively. A partnership of the physicians (often with additional employed physicians) is by far the most common form of organization for the practice of medicine. Ownership of physical assets is also vested in a partnership arrangement among the physicians in nearly half the total number of groups. Of the 84 groups organized as partnerships for the practice of medicine,[8] 30 per cent were incorporated for the ownership of physical assets.[9] The assets of 9 groups were owned by a single physician, although 2 of these groups were partnerships with reference to distribution or share of income.

TABLE 1.—*Ownership of Physical Assets in Medical Groups in Relation to Form of Organization for Practice of Medicine*

		Type of Organization for Practice of Medicine					
					All Physicians Employed by		
Ownership of Physical Assets	Total Groups	Partners Plus Employed	Partners Only	Single Owner Plus Employed	Hospital	Consumers	Industry
				Number of Groups			
Total groups	102	57	27	8	4	3	3
Partners of practitioners	50	30	20	..	..	..	..
Corporation*	26	20	5	..	1	..	..
	9	1	1	7	..	..	..
	3	..	..	..	..	3	..
	3	..	..	..	..	..	3
Nonprofit voluntary hospital or foundation	3	1	..	..	2	..	..
Unknown	8	5	1	1	1	..	..

* This category includes seventeen corporations comprising practitioners only and nine corporations comprising practitioners and nonpractitioners.

Organization for ownership of group assets appears to vary according to size of group.[10] Thus, of the total 26 groups listed as incorporated for this purpose, 3 were small, 10 were medium and 13 were large. The groups sponsored by a nonprofit voluntary hospital or foundation were all large, with 11 or more physicians on their staffs; the "single owner" groups, on the other hand, tended to be small, only 3 of the 9 groups in this category having as many as 6 to 10 physicians.

ADMINISTRATION

The various aspects of administration in medical groups are considered herewith, including considerations such as senior and junior status of partners, professional direction, business management, mode of distribution of income, and the like. Figures 1 and 2 provide a schematic presentation of two characteristic setups in partnership groups.

Authority in Groups.—Authority in a group largely depends on the form of organization of the group. In partnership groups the final authority in matters of policy, professional and business, usually rests with all of the partners collectively or with the senior partners in groups having a senior and junior partnership arrangement. In 14 of 50 groups, an executive committee of several of the partners, or a medical director, seemed to exercise the ultimate authority, yet even in most of these groups all of the partners were consulted in matters of common concern.

Although the final authority in nonprofit voluntary hospital, industrial or consumer cooperative groups may rest with a board of trustees or directors, the board generally relies on the judgment and decisions of some one directly associated with the group. Thus, in the groups intensively studied, full administrative authority was vested in the medical director in the nonprofit and consumer groups, and in the business manager in an industrial group. Available information on groups owned by individual physicians was limited, but authority in such groups, which are usually small in size, presumably rests with the owner, especially in financial matters.

Senior and Junior Partners.—The group partnership is at times composed of senior and junior members. There were 6 such groups in the 14 partnerships intensively studied. The junior partners may own a smaller relative part of the physical assets or none at all, and receive a smaller share of the net income. Some groups allow the junior partners an increasing share of ownership in, and income from, the group in the course of time, while in other groups the junior partners attain senior status and all the perquisites thereof after a set period. In administrative matters the junior partners generally have a voice in the discussion of policy, especially in professional matters, but have no vote. Organizationally, the senior-junior setup permits an increasing measure of participation and responsibility in the affairs of the group by the younger men.

Some groups first employ physicians for a probationary period, at the end of which the employed man either becomes a junior partner (in some instances a full partner) or leaves the group. Appointment of a new member in partnership groups generally requires the agreement of all the partners, although in some cases (10 of 52 groups) the engagement of a new member is left to the medical director, an executive committee, heads of departments or a majority vote of the partners.

The Medical Director.—Most of the groups interviewed had a medical director.[11] In partnership groups a member of the staff may be elected to the office by the partners or, particularly in the smaller groups, a partner may assume the role by virtue of seniority in the group.
